

## CURVATURE FLOWS IN SEMI-RIEMANNIAN MANIFOLDS

CLAUS GERHARDT

ABSTRACT. We prove that the limit hypersurfaces of converging curvature flows are stable, if the initial velocity has a weak sign, and give a survey of the existence and regularity results.

## 1. INTRODUCTION

In this paper we want to give a survey of the existence and regularity results for extrinsic curvature flows in semi-Riemannian manifolds, i.e., Riemannian or Lorentzian ambient spaces, with an emphasis on flows in Lorentzian spaces. In order to treat both cases simultaneously terminology like spacelike, timelike, etc., that only makes sense in a Lorentzian setting should be ignored in the Riemannian case.

The general stability result for the limit hypersurfaces of converging curvature flows in Section 5 is new. The regularity result in Theorem 6.5—especially the time independent  $C^{m+2,\alpha}$ -estimates—for converging curvature flows that are graphs is interesting too.

## 2. NOTATIONS AND PRELIMINARY RESULTS

The main objective of this section is to state the equations of Gauß, Codazzi, and Weingarten for hypersurfaces. In view of the subtle but important difference that is to be seen in the *Gauß equation* depending on the nature of the ambient space—Riemannian or Lorentzian—, which we already mentioned in the introduction, we shall formulate the governing equations of a hypersurface  $M$  in a semi-Riemannian  $(n+1)$ -dimensional space  $N$ , which is either Riemannian or Lorentzian. Geometric quantities in  $N$  will be denoted by  $(\bar{g}_{\alpha\beta}), (\bar{R}_{\alpha\beta\gamma\delta})$ , etc., and those in  $M$  by  $(g_{ij}), (R_{ijkl})$ , etc. Greek indices range from 0 to  $n$  and Latin from 1 to  $n$ ; the summation convention is always used. Generic coordinate systems in  $N$  resp.  $M$  will be denoted by  $(x^\alpha)$  resp.  $(\xi^i)$ . Covariant differentiation will simply be indicated by indices, only in case of possible ambiguity they will be preceded by a semicolon, i.e. for a function  $u$  in  $N$ ,  $(u_\alpha)$  will be the gradient and  $(u_{\alpha\beta})$  the Hessian, but e.g., the covariant derivative of the curvature tensor will be abbreviated by  $\bar{R}_{\alpha\beta\gamma\delta;\epsilon}$ . We also point out that

$$(2.1) \quad \bar{R}_{\alpha\beta\gamma\delta;i} = \bar{R}_{\alpha\beta\gamma\delta;\epsilon} x_i^\epsilon$$

with obvious generalizations to other quantities.

Let  $M$  be a *spacelike* hypersurface, i.e. the induced metric is Riemannian, with a differentiable normal  $\nu$ . We define the signature of  $\nu$ ,  $\sigma = \sigma(\nu)$ , by

$$(2.2) \quad \sigma = \bar{g}_{\alpha\beta} \nu^\alpha \nu^\beta = \langle \nu, \nu \rangle.$$

In case  $N$  is Lorentzian,  $\sigma = -1$ , and  $\nu$  is timelike.

In local coordinates,  $(x^\alpha)$  and  $(\xi^i)$ , the geometric quantities of the spacelike hypersurface  $M$  are connected through the following equations

$$(2.3) \quad x_{ij}^\alpha = -\sigma h_{ij} \nu^\alpha$$

the so-called *Gauß formula*. Here, and also in the sequel, a covariant derivative is always a *full* tensor, i.e.

$$(2.4) \quad x_{ij}^\alpha = x_{,ij}^\alpha - \Gamma_{ij}^k x_k^\alpha + \bar{\Gamma}_{\beta\gamma}^\alpha x_i^\beta x_j^\gamma.$$

The comma indicates ordinary partial derivatives.

In this implicit definition the *second fundamental form*  $(h_{ij})$  is taken with respect to  $-\sigma\nu$ .

The second equation is the *Weingarten equation*

$$(2.5) \quad \nu_i^\alpha = h_i^k x_k^\alpha,$$

where we remember that  $\nu_i^\alpha$  is a full tensor.

Finally, we have the *Codazzi equation*

$$(2.6) \quad h_{ij;k} - h_{ik;j} = \bar{R}_{\alpha\beta\gamma\delta} \nu_i^\alpha x_j^\beta x_k^\gamma x_l^\delta$$

and the *Gauß equation*

$$(2.7) \quad R_{ijkl} = \sigma \{ h_{ik} h_{jl} - h_{il} h_{jk} \} + \bar{R}_{\alpha\beta\gamma\delta} x_i^\alpha x_j^\beta x_k^\gamma x_l^\delta.$$

Here, the signature of  $\nu$  comes into play.

**2.1. Definition.** (i) Let  $F \in C^0(\bar{\Gamma}) \cap C^{2,\alpha}(\Gamma)$  be a strictly monotone curvature function, where  $\Gamma \subset \mathbb{R}^n$  is a convex, open, symmetric cone containing the positive cone, such that

$$(2.8) \quad F|_{\partial\Gamma} = 0 \quad \wedge \quad F|_{\Gamma} > 0.$$

Let  $N$  be semi-Riemannian. A spacelike, orientable<sup>1</sup> hypersurface  $M \subset N$  is called *admissible*, if its principal curvatures with respect to a chosen normal lie in  $\Gamma$ . This definition also applies to subsets of  $M$ .

(ii) Let  $M$  be an admissible hypersurface and  $f$  a function defined in a neighbourhood of  $M$ .  $M$  is said to be an *upper barrier* for the pair  $(F, f)$ , if

$$(2.9) \quad F|_M \geq f$$

(iii) Similarly, a spacelike, orientable hypersurface  $M$  is called a *lower barrier* for the pair  $(F, f)$ , if at the points  $\Sigma \subset M$ , where  $M$  is admissible, there holds

$$(2.10) \quad F|_{\Sigma} \leq f.$$

$\Sigma$  may be empty.

(iv) If we consider the mean curvature function,  $F = H$ , then we suppose  $F$  to be defined in  $\mathbb{R}^n$  and any spacelike, orientable hypersurface is admissible.

One of the assumptions that are used when proving a priori estimates is that there exists a strictly convex function  $\chi \in C^2(\bar{\Omega})$  in a given domain  $\Omega$ . We shall state sufficient geometric conditions guaranteeing the existence of such a function. The lemma below will be valid in Lorentzian as well as Riemannian manifolds, but we formulate and prove it only for the Lorentzian case.

**2.2. Lemma.** *Let  $N$  be globally hyperbolic,  $\mathcal{S}_0$  a Cauchy hypersurface,  $(x^\alpha)$  a special coordinate system associated with  $\mathcal{S}_0$ , and  $\bar{\Omega} \subset N$  be compact. Then, there exists a strictly convex function  $\chi \in C^2(\bar{\Omega})$  provided the level hypersurfaces  $\{x^0 = \text{const}\}$  that intersect  $\bar{\Omega}$  are strictly convex.*

*Proof.* For greater clarity set  $t = x^0$ , i.e.,  $t$  is a globally defined time function. Let  $x = x(\xi)$  be a local representation for  $\{t = \text{const}\}$ , and  $t_i, t_{ij}$  be the covariant derivatives of  $t$  with respect to the induced metric, and  $t_\alpha, t_{\alpha\beta}$  be the covariant derivatives in  $N$ , then

$$(2.11) \quad 0 = t_{ij} = t_{\alpha\beta} x_i^\alpha x_j^\beta + t_\alpha x_{ij}^\alpha,$$

and therefore,

$$(2.12) \quad t_{\alpha\beta} x_i^\alpha x_j^\beta = -t_\alpha x_{ij}^\alpha = -\bar{h}_{ij} t_\alpha \nu^\alpha.$$

Here,  $(\nu^\alpha)$  is past directed, i.e., the right-hand side in (2.12) is positive definite in  $\bar{\Omega}$ , since  $(t_\alpha)$  is also past directed.

---

<sup>1</sup>A hypersurface is said to be orientable, if it has a continuous normal field.

Choose  $\lambda > 0$  and define  $\chi = e^{\lambda t}$ , so that

$$(2.13) \quad \chi_{\alpha\beta} = \lambda^2 e^{\lambda t} t_\alpha t_\beta + \lambda e^{\lambda t} t_{\alpha\beta}.$$

Let  $p \in \Omega$  be arbitrary,  $\mathcal{S} = \{t = t(p)\}$  be the level hypersurface through  $p$ , and  $(\eta^\alpha) \in T_p(N)$ . Then, we conclude

$$(2.14) \quad e^{-\lambda t} \chi_{\alpha\beta} \eta^\alpha \eta^\beta = \lambda^2 |\eta^0|^2 + \lambda t_{ij} \eta^i \eta^j + 2\lambda t_{0j} \eta^0 \eta^j,$$

where  $t_{ij}$  now represents the left-hand side in (2.12), and we infer further

$$(2.15) \quad \begin{aligned} e^{-\lambda t} \chi_{\alpha\beta} \eta^\alpha \eta^\beta &\geq \frac{1}{2} \lambda^2 |\eta^0|^2 + [\lambda\epsilon - c_\epsilon] \sigma_{ij} \eta^i \eta^j \\ &\geq \frac{\epsilon}{2} \lambda \{-|\eta^0|^2 + \sigma_{ij} \eta^i \eta^j\} \end{aligned}$$

for some  $\epsilon > 0$ , and where  $\lambda$  is supposed to be large. Therefore, we have in  $\bar{\Omega}$

$$(2.16) \quad \chi_{\alpha\beta} \geq c \bar{g}_{\alpha\beta}, \quad c > 0,$$

i.e.,  $\chi$  is strictly convex.  $\square$

### 3. EVOLUTION EQUATIONS FOR SOME GEOMETRIC QUANTITIES

Curvature flows are used for different purposes, they can be merely vehicles to approximate a stationary solution, in which case the flow is driven not only by a curvature function but also by the corresponding right-hand side, an external force, if you like, or the flow is a pure curvature flow driven only by a curvature function, and it is used to analyze the topology of the initial hypersurface, if the ambient space is Riemannian, or the singularities of the ambient space, in the Lorentzian case.

In this section we are treating very general curvature flows<sup>2</sup> in a semi-Riemannian manifold  $N = N^{n+1}$ , though we only have the Riemannian or Lorentzian case in mind, such that the flow can be either a pure curvature flow or may also be driven by an external force. The nature of the ambient space, i.e., the signature of its metric, is expressed by a parameter  $\sigma = \pm 1$ , such that  $\sigma = 1$  corresponds to the Riemannian and  $\sigma = -1$  the Lorentzian case. The parameter  $\sigma$  can also be viewed as the signature of the normal of the spacelike hypersurfaces, namely,

$$(3.1) \quad \sigma = \langle \nu, \nu \rangle.$$

Properties like spacelike, achronal, etc., however, only make sense, when  $N$  is Lorentzian and should be ignored otherwise.

We consider a strictly monotone, symmetric, and concave curvature  $F \in C^{4,\alpha}(I)$ , homogeneous of degree 1, a function  $0 < f \in C^{4,\alpha}(\Omega)$ , where  $\Omega \subset N$  is an open set, and a real function  $\Phi \in C^{4,\alpha}(\mathbb{R}_+)$  satisfying

$$(3.2) \quad \dot{\Phi} > 0 \quad \text{and} \quad \ddot{\Phi} \leq 0.$$

For notational reasons, let us abbreviate

$$(3.3) \quad \tilde{f} = \Phi(f).$$

---

<sup>2</sup>We emphasize that we are only considering flows driven by the extrinsic curvature not by the intrinsic curvature.

Important examples of functions  $\Phi$  are

$$(3.4) \quad \Phi(r) = r, \quad \Phi(r) = \log r, \quad \Phi(r) = -r^{-1}$$

or

$$(3.5) \quad \Phi(r) = r^{\frac{1}{k}}, \quad \Phi(r) = -r^{-\frac{1}{k}}, \quad k \geq 1.$$

**3.1. Remark.** The latter choices are necessary, if the curvature function  $F$  is not homogeneous of degree 1 but of degree  $k$ , like the symmetric polynomials  $H_k$ . In this case we would sometimes like to define  $F = H_k$  and not  $H_k^{1/k}$ , since

$$(3.6) \quad F^{ij} = \frac{\partial F}{\partial h_{ij}}$$

is then divergence free, if the ambient space is a spaceform, cf. Lemma 5.8 on page 24, though on the other hand we need a concave operator for technical reasons, hence we have to take the  $k$ -th root.

The curvature flow is given by the evolution problem

$$(3.7) \quad \begin{aligned} \dot{x} &= -\sigma(\Phi - \tilde{f})\nu, \\ x(0) &= x_0, \end{aligned}$$

where  $x_0$  is an embedding of an initial compact, spacelike hypersurface  $M_0 \subset \Omega$  of class  $C^{6,\alpha}$ ,  $\Phi = \Phi(F)$ , and  $F$  is evaluated at the principal curvatures of the flow hypersurfaces  $M(t)$ , or, equivalently, we may assume that  $F$  depends on the second fundamental form  $(h_{ij})$  and the metric  $(g_{ij})$  of  $M(t)$ ;  $x(t)$  is the embedding of  $M(t)$  and  $\sigma$  the signature of the normal  $\nu = \nu(t)$ , which is identical to the normal used in the Gaussian formula (2.3) on page 2.

The initial hypersurface should be *admissible*, i.e., its principal curvatures should belong to the convex, symmetric cone  $\Gamma \subset \mathbb{R}^n$ .

This is a parabolic problem, so short-time existence is guaranteed, cf. [18, Chapter 2.5]

There will be a slight ambiguity in the terminology, since we shall call the evolution parameter *time*, but this lapse shouldn't cause any misunderstandings, if the ambient space is Lorentzian.

At the moment we consider a sufficiently smooth solution of the initial value problem (3.7) and want to show how the metric, the second fundamental form, and the normal vector of the hypersurfaces  $M(t)$  evolve. All time derivatives are *total* derivatives, i.e., covariant derivatives of tensor fields defined over the curve  $x(t)$ , cf. [17, Chapter 11.5];  $t$  is the flow parameter, also referred to as *time*, and  $(\xi^i)$  are local coordinates of the initial embedding  $x_0 = x_0(\xi)$  which will also serve as coordinates for the flow hypersurfaces  $M(t)$ . The coordinates in  $N$  will be labelled  $(x^\alpha)$ ,  $0 \leq \alpha \leq n$ .

**3.2. Lemma** (Evolution of the metric). *The metric  $g_{ij}$  of  $M(t)$  satisfies the evolution equation*

$$(3.8) \quad \dot{g}_{ij} = -2\sigma(\Phi - \tilde{f})h_{ij}.$$

*Proof.* Differentiating

$$(3.9) \quad g_{ij} = \langle x_i, x_j \rangle$$

covariantly with respect to  $t$  yields

$$(3.10) \quad \begin{aligned} \dot{g}_{ij} &= \langle \dot{x}_i, x_j \rangle + \langle x_i, \dot{x}_j \rangle \\ &= -2\sigma(\Phi - \tilde{f})\langle x_i, \nu_j \rangle = -2\sigma(\Phi - \tilde{f})h_{ij}, \end{aligned}$$

in view of the Codazzi equations.  $\square$

**3.3. Lemma** (Evolution of the normal). *The normal vector evolves according to*

$$(3.11) \quad \dot{\nu} = \nabla_M(\Phi - \tilde{f}) = g^{ij}(\Phi - \tilde{f})_i x_j.$$

*Proof.* Since  $\nu$  is unit normal vector we have  $\dot{\nu} \in T(M)$ . Furthermore, differentiating

$$(3.12) \quad 0 = \langle \nu, x_i \rangle$$

with respect to  $t$ , we deduce

$$(3.13) \quad \langle \dot{\nu}, x_i \rangle = -\langle \nu, \dot{x}_i \rangle = (\Phi - \tilde{f})_i. \quad \square$$

**3.4. Lemma** (Evolution of the second fundamental form). *The second fundamental form evolves according to*

$$(3.14) \quad \dot{h}_i^j = (\Phi - \tilde{f})_i^j + \sigma(\Phi - \tilde{f})h_i^k h_k^j + \sigma(\Phi - \tilde{f})\bar{R}_{\alpha\beta\gamma\delta}\nu^\alpha x_i^\beta \nu^\gamma x_k^\delta g^{kj}$$

and

$$(3.15) \quad \dot{h}_{ij} = (\Phi - \tilde{f})_{ij} - \sigma(\Phi - \tilde{f})h_i^k h_{kj} + \sigma(\Phi - \tilde{f})\bar{R}_{\alpha\beta\gamma\delta}\nu^\alpha x_i^\beta \nu^\gamma x_j^\delta.$$

*Proof.* We use the *Ricci identities* to interchange the covariant derivatives of  $\nu$  with respect to  $t$  and  $\xi^i$

$$(3.16) \quad \begin{aligned} \frac{D}{dt}(\nu_i^\alpha) &= (\dot{\nu}^\alpha)_i - \bar{R}^\alpha_{\beta\gamma\delta}\nu^\beta x_i^\gamma \dot{x}^\delta \\ &= g^{kl}(\Phi - \tilde{f})_{ki}x_l^\alpha + g^{kl}(\Phi - \tilde{f})_k x_{li}^\alpha - \bar{R}^\alpha_{\beta\gamma\delta}\nu^\beta x_i^\gamma \dot{x}^\delta. \end{aligned}$$

For the second equality we used (3.11). On the other hand, in view of the Weingarten equation we obtain

$$(3.17) \quad \frac{D}{dt}(\nu_i^\alpha) = \frac{D}{dt}(h_i^k x_k^\alpha) = \dot{h}_i^k x_k^\alpha + h_i^k \dot{x}_k^\alpha.$$

Multiplying the resulting equation with  $\bar{g}_{\alpha\beta}x_j^\beta$  we conclude

$$(3.18) \quad \dot{h}_i^k g_{kj} - \sigma(\Phi - \tilde{f})h_i^k h_{kj} = (\Phi - \tilde{f})_{ij} + \sigma(\Phi - \tilde{f})\bar{R}_{\alpha\beta\gamma\delta}\nu^\alpha x_i^\beta \nu^\gamma x_j^\delta$$

or equivalently (3.14).

To derive (3.15), we differentiate

$$(3.19) \quad h_{ij} = h_i^k g_{kj}$$

with respect to  $t$  and use (3.8).  $\square$

We emphasize that equation (3.14) describes the evolution of the second fundamental form more meaningfully than (3.15), since the mixed tensor is independent of the metric.

**3.5. Lemma** (Evolution of  $(\Phi - \tilde{f})$ ). *The term  $(\Phi - \tilde{f})$  evolves according to the equation*

$$(3.20) \quad (\Phi - \tilde{f})' - \dot{\Phi} F^{ij} (\Phi - \tilde{f})_{ij} = \sigma \dot{\Phi} F^{ij} h_{ik} h_j^k (\Phi - \tilde{f}) + \sigma \tilde{f}_\alpha \nu^\alpha (\Phi - \tilde{f}) \\ + \sigma \dot{\Phi} F^{ij} \bar{R}_{\alpha\beta\gamma\delta} \nu^\alpha x_i^\beta \nu^\gamma x_j^\delta (\Phi - \tilde{f}),$$

where

$$(3.21) \quad (\Phi - \tilde{f})' = \frac{d}{dt}(\Phi - \tilde{f})$$

and

$$(3.22) \quad \dot{\Phi} = \frac{d}{dr}\Phi(r).$$

*Proof.* When we differentiate  $F$  with respect to  $t$  we consider  $F$  to depend on the mixed tensor  $h_i^j$  and conclude

$$(3.23) \quad (\Phi - \tilde{f})' = \dot{\Phi} F_j^i h_i^j - \tilde{f}_\alpha \dot{x}^\alpha;$$

The equation (3.20) then follows in view of (3.7) and (3.14).  $\square$

**3.6. Remark.** The preceding conclusions, except Lemma 3.5, remain valid for flows which do not depend on the curvature, i.e., for flows

$$(3.24) \quad \dot{x} = -\sigma(-f)\nu = \sigma f\nu, \\ x(0) = x_0,$$

where  $f = f(x)$  is defined in an open set  $\Omega$  containing the initial spacelike hypersurface  $M_0$ . In the preceding equations we only have to set  $\Phi = 0$  and  $\tilde{f} = f$ .

The evolution equation for the mean curvature then looks like

$$(3.25) \quad \dot{H} = -\Delta f - \sigma\{|A|^2 + \bar{R}_{\alpha\beta}\nu^\alpha\nu^\beta\}f,$$

where the Laplacian is the Laplace operator on the hypersurface  $M(t)$ . This is exactly the derivative of the mean curvature operator with respect to normal variations as we shall see in a moment.

But first let us consider the following example.

**3.7. Example.** Let  $(x^\alpha)$  be a future directed Gaussian coordinate system in  $N$ , such that the metric can be expressed in the form

$$(3.26) \quad d\bar{s}^2 = e^{2\psi}\{\sigma(dx^0)^2 + \sigma_{ij}dx^i dx^j\}.$$

Denote by  $M(t)$  the coordinate slices  $\{x^0 = t\}$ , then  $M(t)$  can be looked at as the flow hypersurfaces of the flow

$$(3.27) \quad \dot{x} = -\sigma(-e^\psi)\bar{\nu},$$

where we denote the geometric quantities of the slices by  $\bar{g}_{ij}$ ,  $\bar{\nu}$ ,  $\bar{h}_{ij}$ , etc.

Here  $x$  is the embedding

$$(3.28) \quad x = x(t, \xi^i) = (t, x^i).$$

Notice that, if  $N$  is Riemannian, the coordinate system and the normal are always chosen such that  $\nu^0 > 0$ , while, if  $N$  is Lorentzian, we always pick the past directed normal.

Hence the mean curvature of the slices evolves according to

$$(3.29) \quad \dot{\bar{H}} = -\Delta e^\psi - \sigma\{|\bar{A}|^2 + \bar{R}_{\alpha\beta}\bar{\nu}^\alpha\bar{\nu}^\beta\}e^\psi.$$

We can now derive the linearization of the mean curvature operator of a spacelike hypersurface, compact or non-compact.

**3.8.** Let  $M_0 \subset N$  be a spacelike hypersurface of class  $C^4$ . We first assume that  $M_0$  is compact; then there exists a tubular neighbourhood  $\mathcal{U}$  and a corresponding *normal* Gaussian coordinate system  $(x^\alpha)$  of class  $C^3$  such that  $\frac{\partial}{\partial x^\sigma}$  is normal to  $M_0$ .

Let us consider in  $\mathcal{U}$  of  $M_0$  spacelike hypersurfaces  $M$  that can be written as graphs over  $M_0$ ,  $M = \text{graph } u$ , in the corresponding normal Gaussian coordinate system. Then the mean curvature of  $M$  can be expressed as

$$(3.30) \quad H = \{-\Delta u + \bar{H} - \sigma v^{-2} u^i u^j \bar{h}_{ij}\}v,$$

where  $\sigma = \langle \nu, \nu \rangle$ , and hence, choosing  $u = \epsilon\varphi$ ,  $\varphi \in C^2(M_0)$ , we deduce

$$(3.31) \quad \begin{aligned} \frac{d}{d\epsilon} H|_{\epsilon=0} &= -\Delta\varphi + \dot{\bar{H}}\varphi \\ &= -\Delta\varphi - \sigma(|\bar{A}|^2 + \bar{R}_{\alpha\beta}\nu^\alpha\nu^\beta)\varphi, \end{aligned}$$

in view of (3.29).

The right-hand side is the derivative of the mean curvature operator applied to  $\varphi$ .

If  $M_0$  is non-compact, tubular neighbourhoods exist locally and the relation (3.31) will be valid for any  $\varphi \in C_c^2(M_0)$  by using a partition of unity.

The preceding linearization can be immediately generalized to a hypersurface  $M_0$  solving the equation

$$(3.32) \quad F|_{M_0} = f,$$

where  $f = f(x)$  is defined in a neighbourhood of  $M_0$  and  $F = F(h_{ij})$  is curvature operator.

**3.9. Lemma.** *Let  $M_0$  be of class  $C^{m,\alpha}$ ,  $m \geq 2$ ,  $0 \leq \alpha \leq 1$ , satisfy (3.32). Let  $\mathcal{U}$  be a (local) tubular neighbourhood of  $M_0$ , then the linearization of the operator  $F - f$  expressed in the normal Gaussian coordinate system  $(x^\alpha)$  corresponding to  $\mathcal{U}$  and evaluated at  $M_0$  has the form*

$$(3.33) \quad -F^{ij}u_{ij} - \sigma\{F^{ij}h_i^k h_{kj} + F^{ij}\bar{R}_{\alpha\beta\gamma\delta}\nu^\alpha x_i^\beta \nu^\gamma x_j^\delta + f_\alpha \nu^\alpha\}u,$$

where  $u$  is a function defined in  $M_0$ , and all geometric quantities are those of  $M_0$ ; the derivatives are covariant derivatives with respect to the induced metric of  $M_0$ . The operator will be self-adjoint, if  $F^{ij}$  is divergence free.

*Proof.* For simplicity assume that  $M_0$  is compact, and let  $u \in C^2(M_0)$  be fixed. Then the hypersurfaces

$$(3.34) \quad M_\epsilon = \text{graph}(\epsilon u)$$

stay in the tubular neighbourhood  $\mathcal{U}$  for small  $\epsilon$ ,  $|\epsilon| < \epsilon_0$ , and their second fundamental forms  $(h_{ij})$  can be expressed as

$$(3.35) \quad v^{-1}h_{ij} = -(\epsilon u)_{ij} + \bar{h}_{ij},$$

where  $\bar{h}_{ij}$  is the second fundamental form of the coordinate slices  $\{x^0 = \text{const}\}$ .

We are interested in

$$(3.36) \quad \frac{d}{d\epsilon}(F - f)|_{\epsilon=0}.$$

To differentiate  $F$  with respect to  $\epsilon$  it is best to consider the mixed form  $(h_i^j)$  of the second fundamental form to derive

$$(3.37) \quad \frac{d}{d\epsilon}(F - f) = F_j^i \dot{h}_i^j - \frac{\partial f}{\partial x^0} u = -F^{ij} u_{ij} + F_j^i \dot{\bar{h}}_i^j u - \frac{\partial f}{\partial x^0} u,$$

where the equation is evaluated at  $\epsilon = 0$  and  $\dot{\bar{h}}_i^j$  is the derivative of  $\bar{h}_i^j$  with respect to  $x^0$ .

The result then follows from the evolution equation (3.14) for the flow (3.27), i.e., we have to replace  $(\Phi - \tilde{f})$  in (3.14) by  $-1$ .  $\square$

#### 4. ESSENTIAL PARABOLIC FLOW EQUATIONS

From (3.14) on page 6 we deduce with the help of the Ricci identities a parabolic equation for the second fundamental form

**4.1. Lemma.** *The mixed tensor  $h_i^j$  satisfies the parabolic equation*

$$(4.1) \quad \begin{aligned} & \dot{h}_i^j - \dot{\Phi} F^{kl} h_{i;kl}^j = \\ & \sigma \dot{\Phi} F^{kl} h_{rk} h_l^r h_i^j - \sigma \dot{\Phi} F h_{ri} h^{rj} + \sigma(\Phi - \tilde{f}) h_i^k h_k^j \\ & - \tilde{f}_{\alpha\beta} x_i^\alpha x_k^\beta g^{kj} + \sigma \tilde{f}_\alpha \nu^\alpha h_i^j + \dot{\Phi} F^{kl,rs} h_{kl;i} h_{rs;j} \\ & + \ddot{\Phi} F_i F^j + 2\dot{\Phi} F^{kl} \bar{R}_{\alpha\beta\gamma\delta} x_m^\alpha x_i^\beta x_k^\gamma x_l^\delta h_l^m g^{rj} \\ & - \dot{\Phi} F^{kl} \bar{R}_{\alpha\beta\gamma\delta} x_m^\alpha x_k^\beta x_r^\gamma x_l^\delta h_i^m g^{rj} - \dot{\Phi} F^{kl} \bar{R}_{\alpha\beta\gamma\delta} x_m^\alpha x_k^\beta x_i^\gamma x_l^\delta h^{mj} \\ & + \sigma \dot{\Phi} F^{kl} \bar{R}_{\alpha\beta\gamma\delta} \nu^\alpha x_k^\beta \nu^\gamma x_l^\delta h_i^j - \sigma \dot{\Phi} F \bar{R}_{\alpha\beta\gamma\delta} \nu^\alpha x_i^\beta \nu^\gamma x_m^\delta g^{mj} \\ & + \sigma(\Phi - \tilde{f}) \bar{R}_{\alpha\beta\gamma\delta} \nu^\alpha x_i^\beta \nu^\gamma x_m^\delta g^{mj} \\ & + \dot{\Phi} F^{kl} \bar{R}_{\alpha\beta\gamma\delta;\epsilon} \{ \nu^\alpha x_k^\beta x_l^\gamma x_i^\delta x_m^\epsilon g^{mj} + \nu^\alpha x_i^\beta x_k^\gamma x_m^\delta x_l^\epsilon g^{mj} \}. \end{aligned}$$

*Proof.* We start with equation (3.14) on page 6 and shall evaluate the term

$$(4.2) \quad (\Phi - \tilde{f})_i^j;$$

since we are only working with covariant spatial derivatives in the subsequent proof, we may—and shall—consider the covariant form of the tensor

$$(4.3) \quad (\Phi - \tilde{f})_{ij}.$$

First we have

$$(4.4) \quad \Phi_i = \dot{\Phi} F_i = \dot{\Phi} F^{kl} h_{kl;i}$$

and

$$(4.5) \quad \Phi_{ij} = \dot{\Phi} F^{kl} h_{kl;ij} + \ddot{\Phi} F^{kl} h_{kl;i} F^{rs} h_{rs;j} + \dot{\Phi} F^{kl,rs} h_{kl;;i} h_{rs;j}.$$

Next, we want to replace  $h_{kl;ij}$  by  $h_{ij;kl}$ . Differentiating the Codazzi equation

$$(4.6) \quad h_{kl;i} = h_{ik;l} + \bar{R}_{\alpha\beta\gamma\delta} \nu^\alpha x_k^\beta x_l^\gamma x_i^\delta,$$

where we also used the symmetry of  $h_{ik}$ , yields

$$(4.7) \quad \begin{aligned} h_{kl;ij} &= h_{ik;l;j} + \bar{R}_{\alpha\beta\gamma\delta;\epsilon} \nu^\alpha x_k^\beta x_l^\gamma x_i^\delta x_j^\epsilon \\ &\quad + \bar{R}_{\alpha\beta\gamma\delta} \{ \nu_j^\alpha x_k^\beta x_l^\gamma x_i^\delta + \nu^\alpha x_{kj}^\beta x_l^\gamma x_i^\delta + \nu^\alpha x_k^\beta x_{lj}^\gamma x_i^\delta + \nu^\alpha x_k^\beta x_l^\gamma x_{ij}^\delta \}. \end{aligned}$$

To replace  $h_{kl;ij}$  by  $h_{ij;kl}$  we use the Ricci identities

$$(4.8) \quad h_{ik;l;j} = h_{ik;j;l} + h_{ak} R^a_{ilj} + h_{ai} R^a_{klj}$$

and differentiate once again the Codazzi equation

$$(4.9) \quad h_{ik;j} = h_{ij;k} + \bar{R}_{\alpha\beta\gamma\delta} \nu^\alpha x_i^\beta x_k^\gamma x_j^\delta.$$

To replace  $\tilde{f}_{ij}$  we use the chain rule

$$(4.10) \quad \begin{aligned} \tilde{f}_i &= \tilde{f}_\alpha x_i^\alpha, \\ \tilde{f}_{ij} &= \tilde{f}_{\alpha\beta} x_i^\alpha x_j^\beta + \tilde{f}_\alpha x_{ij}^\alpha. \end{aligned}$$

Then, because of the Gauß equation, Gaussian formula, and Weingarten equation, the symmetry properties of the Riemann curvature tensor and the assumed homogeneity of  $F$ , i.e.,

$$(4.11) \quad F = F^{kl} h_{kl},$$

we deduce (4.1) from (3.14) on page 6 after reverting to the mixed representation.  $\square$

**4.2. Remark.** If we had assumed  $F$  to be homogeneous of degree  $d_0$  instead of 1, then we would have to replace the explicit term  $F$ —occurring twice in the preceding lemma—by  $d_0 F$ .

If the ambient semi-Riemannian manifold is a space of constant curvature, then the evolution equation of the second fundamental form simplifies considerably, as can be easily verified.

**4.3. Lemma.** *Let  $N$  be a space of constant curvature  $K_N$ , then the second fundamental form of the curvature flow (3.7) on page 5 satisfies the parabolic equation*

$$\begin{aligned}
 \dot{h}_i^j - \dot{\Phi} F^{kl} h_{i;kl}^j &= \sigma \dot{\Phi} F^{kl} h_{rk} h_l^r h_i^j - \sigma \dot{\Phi} F h_{ri} h^{rj} + \sigma(\Phi - \tilde{f}) h_i^k h_k^j \\
 &\quad - \tilde{f}_{\alpha\beta} x_i^\alpha x_k^\beta g^{kj} + \sigma \tilde{f}_\alpha \nu^\alpha h_i^j + \dot{\Phi} F^{kl,rs} h_{kl;i} h_{rs;j} \\
 &\quad + \ddot{\Phi} F_i F^j \\
 &\quad + K_N \{ (\Phi - \tilde{f}) \delta_i^j + \dot{\Phi} F \delta_i^j - \dot{\Phi} F^{kl} g_{kl} h_i^j \}.
 \end{aligned}
 \tag{4.12}$$

Let us now assume that the open set  $\Omega \subset N$  containing the flow hypersurfaces can be covered by a Gaussian coordinate system  $(x^\alpha)$ , i.e.,  $\Omega$  can be topologically viewed as a subset of  $I \times \mathcal{S}_0$ , where  $\mathcal{S}_0$  is a compact Riemannian manifold and  $I$  an interval. We assume furthermore, that the flow hypersurfaces can be written as graphs over  $\mathcal{S}_0$

$$M(t) = \{ x^0 = u(x^i) : x = (x^i) \in \mathcal{S}_0 \}; \tag{4.13}$$

we use the symbol  $x$  ambiguously by denoting points  $p = (x^\alpha) \in N$  as well as points  $p = (x^i) \in \mathcal{S}_0$  simply by  $x$ , however, we are careful to avoid confusions.

Suppose that the flow hypersurfaces are given by an embedding  $x = x(t, \xi)$ , where  $\xi = (\xi^i)$  are local coordinates of a compact manifold  $M_0$ , which then has to be homeomorphic to  $\mathcal{S}_0$ , then

$$\begin{aligned}
 x^0 &= u(t, \xi) = u(t, x(t, \xi)), \\
 x^i &= x^i(t, \xi).
 \end{aligned}
 \tag{4.14}$$

The induced metric can be expressed as

$$g_{ij} = \langle x_i, x_j \rangle = \sigma u_i u_j + \sigma_{kl} x_i^k x_j^l, \tag{4.15}$$

where

$$u_i = u_k x_i^k, \tag{4.16}$$

i.e.,

$$g_{ij} = \{ \sigma u_k u_l + \sigma_{kl} \} x_i^k x_j^l, \tag{4.17}$$

hence the (time dependent) *Jacobian*  $(x_i^k)$  is invertible, and the  $(\xi^i)$  can also be viewed as coordinates for  $\mathcal{S}_0$ .

Looking at the component  $\alpha = 0$  of the flow equation (3.7) on page 5 we obtain a scalar flow equation

$$\dot{u} = -e^{-\psi} v^{-1} (\Phi - \tilde{f}), \tag{4.18}$$

which is the same in the Lorentzian as well as in the Riemannian case, where

$$v^2 = 1 - \sigma \sigma^{ij} u_i u_j, \tag{4.19}$$

and where

$$|Du|^2 = \sigma^{ij} u_i u_j \tag{4.20}$$

is of course a scalar, i.e., we obtain the same expression regardless, if we use the coordinates  $x^i$  or  $\xi^i$ .

The time derivative in (4.18) is a total time derivative, if we consider  $u$  to depend on  $u = u(t, x(t, \xi))$ . For the partial time derivative we obtain

$$(4.21) \quad \begin{aligned} \frac{\partial u}{\partial t} &= \dot{u} - u_k \dot{x}_i^k \\ &= -e^{-\psi} v (\Phi - \tilde{f}), \end{aligned}$$

in view of (3.7) on page 5 and our choice of normal  $\nu = (\nu^\alpha)$

$$(4.22) \quad (\nu^\alpha) = \sigma e^{-\psi} v^{-1} (1, -\sigma u^i),$$

where  $u^i = \sigma^{ij} u_j$ .

Controlling the  $C^1$ -norm of the graphs  $M(t)$  is tantamount to controlling  $v$ , if  $N$  is Riemannian, and  $\tilde{v} = v^{-1}$ , if  $N$  is Lorentzian. The evolution equations satisfied by these quantities are also very important, since they are used for the a priori estimates of the second fundamental form.

Let us start with the Lorentzian case.

**4.4. Lemma** (Evolution of  $\tilde{v}$ ). *Consider the flow (3.7) in a Lorentzian space  $N$  such that the spacelike flow hypersurfaces can be written as graphs over  $\mathcal{S}_0$ . Then,  $\tilde{v}$  satisfies the evolution equation*

$$(4.23) \quad \begin{aligned} \dot{\tilde{v}} - \dot{\Phi} F^{ij} \tilde{v}_{ij} &= -\dot{\Phi} F^{ij} h_{ik} h_j^k \tilde{v} + [(\Phi - \tilde{f}) - \dot{\Phi} F] \eta_{\alpha\beta} \nu^\alpha \nu^\beta \\ &\quad - 2\dot{\Phi} F^{ij} h_j^k x_i^\alpha x_k^\beta \eta_{\alpha\beta} - \dot{\Phi} F^{ij} \eta_{\alpha\beta\gamma} x_i^\beta x_j^\gamma \nu^\alpha \\ &\quad - \dot{\Phi} F^{ij} \bar{R}_{\alpha\beta\gamma\delta} \nu^\alpha x_i^\beta x_j^\gamma \eta_\epsilon x_l^\epsilon g^{kl} \\ &\quad - \tilde{f}_\beta x_i^\beta x_k^\alpha \eta_\alpha g^{ik}, \end{aligned}$$

where  $\eta$  is the covariant vector field  $(\eta_\alpha) = e^\psi(-1, 0, \dots, 0)$ .

*Proof.* We have  $\tilde{v} = \langle \eta, \nu \rangle$ . Let  $(\xi^i)$  be local coordinates for  $M(t)$ . Differentiating  $\tilde{v}$  covariantly we deduce

$$(4.24) \quad \tilde{v}_i = \eta_{\alpha\beta} x_i^\beta \nu^\alpha + \eta_\alpha \nu_i^\alpha,$$

$$(4.25) \quad \begin{aligned} \tilde{v}_{ij} &= \eta_{\alpha\beta\gamma} x_i^\beta x_j^\gamma \nu^\alpha + \eta_{\alpha\beta} x_{ij}^\beta \nu^\alpha \\ &\quad + \eta_{\alpha\beta} x_i^\beta \nu_j^\alpha + \eta_{\alpha\beta} x_j^\beta \nu_i^\alpha + \eta_\alpha \nu_{ij}^\alpha \end{aligned}$$

The time derivative of  $\tilde{v}$  can be expressed as

$$(4.26) \quad \begin{aligned} \dot{\tilde{v}} &= \eta_{\alpha\beta} \dot{x}^\beta \nu^\alpha + \eta_\alpha \dot{\nu}^\alpha \\ &= \eta_{\alpha\beta} \nu^\alpha \nu^\beta (\Phi - \tilde{f}) + (\Phi - \tilde{f})^k x_k^\alpha \eta_\alpha \\ &= \eta_{\alpha\beta} \nu^\alpha \nu^\beta (\Phi - \tilde{f}) + \dot{\Phi} F^k x_k^\alpha \eta_\alpha - \tilde{f}_\beta x_i^\beta x_k^\alpha g^{ik} \eta_\alpha, \end{aligned}$$

where we have used (3.11) on page 6.

Substituting (4.25) and (4.26) in (4.23), and simplifying the resulting equation with the help of the Weingarten and Codazzi equations, we arrive at the desired conclusion.  $\square$

In the Riemannian case we consider a normal Gaussian coordinate system  $(x^\alpha)$ , for otherwise we won't obtain a priori estimates for  $v$ , at least not without additional strong assumptions. We also refer to  $x^0 = r$  as the *radial distance function*.

**4.5. Lemma** (Evolution of  $v$ ). *Consider the flow (3.7) in a normal Gaussian coordinate system where the  $M(t)$  can be written as graphs of a function  $u(t)$  over some compact Riemannian manifold  $S_0$ . Then the quantity*

$$(4.27) \quad v = \sqrt{1 + |Du|^2} = (r_\alpha \nu^\alpha)^{-1}$$

satisfies the evolution equation

$$(4.28) \quad \begin{aligned} \dot{v} - \dot{\Phi} F^{ij} v_{ij} &= -\dot{\Phi} F^{ij} h_{ik} h_j^k v - 2v^{-1} \dot{\Phi} F^{ij} v_i v_j \\ &+ r_{\alpha\beta} \nu^\alpha \nu^\beta [(\Phi - \tilde{f}) - \dot{\Phi} F] v^2 + 2\dot{\Phi} F^{ij} h_i^k r_{\alpha\beta} x_k^\alpha x_j^\beta v^2 \\ &+ \dot{\Phi} F^{ij} \bar{R}_{\alpha\beta\gamma\delta} \nu^\alpha x_i^\beta x_j^\gamma x_k^\delta r_\epsilon x_m^\epsilon g^{mk} v^2 \\ &+ \dot{\Phi} F^{ij} r_{\alpha\beta\gamma} \nu^\alpha x_i^\beta x_j^\gamma v^2 + \tilde{f}_\alpha x_m^\alpha g^{mk} r_\beta x_k^\beta v^2. \end{aligned}$$

*Proof.* Similar to the proof of the previous lemma.  $\square$

The previous problems can be generalized to the case when the right-hand side  $f$  is not only defined in  $N$  or in  $\bar{\Omega}$  but in the *tangent bundle*  $T(N)$  resp.  $T(\bar{\Omega})$ . Notice that the tangent bundle is a manifold of dimension  $2(n+1)$ , i.e., in a *local trivialization* of  $T(N)$   $f$  can be expressed in the form

$$(4.29) \quad f = f(x, \nu)$$

with  $x \in N$  and  $\nu \in T_x(N)$ , cf. [17, Note 12.2.14]. Thus, the case  $f = f(x)$  is included in this general set up. The symbol  $\nu$  indicates that in an equation

$$(4.30) \quad F|_M = f$$

we want  $f$  to be evaluated at  $(x, \nu)$ , where  $x \in M$  and  $\nu$  is the normal of  $M$  in  $x$ .

The *Minkowski problem* or *Minkowski type problems* are also covered by the present setting, though the Minkowski problem has the additional property that the problem is transformed via the *Gauß map* to a different semi-Riemannian manifold as a *dual problem* and solved there. Minkowski type problems have been treated in [5], [23], [16] and [21].

**4.6. Remark.** The equation (4.30) will be solved by the same methods as in the special case when  $f = f(x)$ , i.e., we consider the same curvature flow, the evolution equation (3.7) on page 5, as before.

The resulting evolution equations are identical with the natural exception, that, when  $f$  or  $\tilde{f}$  has to be differentiated, the additional argument has to be considered, e.g.,

$$(4.31) \quad \tilde{f}_i = \tilde{f}_\alpha x_i^\alpha + \tilde{f}_{\nu\beta} \nu_i^\beta = \tilde{f}_\alpha x_i^\alpha + \tilde{f}_{\nu\beta} x_k^\beta h_i^k$$

and

$$(4.32) \quad \dot{\tilde{f}} = \tilde{f}_\alpha \dot{x}^\alpha + \tilde{f}_{\nu\beta} \dot{\nu}^\beta = -\sigma(\Phi - \tilde{f}) \tilde{f}_\alpha \nu^\alpha + \tilde{f}_{\nu\beta} g^{ij} (\Phi - \tilde{f})_i x_j^\beta.$$

The most important evolution equations are explicitly stated below.

Let us first state the evolution equation for  $(\Phi - \tilde{f})$ .

**4.7. Lemma** (Evolution of  $(\Phi - \tilde{f})$ ). *The term  $(\Phi - \tilde{f})$  evolves according to the equation*

$$(4.33) \quad \begin{aligned} (\Phi - \tilde{f})' - \dot{\Phi} F^{ij} (\Phi - \tilde{f})_{ij} &= \sigma \dot{\Phi} F^{ij} h_{ik} h_j^k (\Phi - \tilde{f}) \\ &+ \sigma \tilde{f}_\alpha \nu^\alpha (\Phi - \tilde{f}) - \tilde{f}_{\nu^\alpha} x_i^\alpha (\Phi - \tilde{f})_j g^{ij} \\ &+ \sigma \dot{\Phi} F^{ij} \bar{R}_{\alpha\beta\gamma\delta} \nu^\alpha x_i^\beta \nu^\gamma x_j^\delta (\Phi - \tilde{f}), \end{aligned}$$

where

$$(4.34) \quad (\Phi - \tilde{f})' = \frac{d}{dt} (\Phi - \tilde{f})$$

and

$$(4.35) \quad \dot{\Phi} = \frac{d}{dr} \Phi(r).$$

Here is the evolution equation for the second fundamental form.

**4.8. Lemma.** *The mixed tensor  $h_i^j$  satisfies the parabolic equation*

$$(4.36) \quad \begin{aligned} \dot{h}_i^j - \dot{\Phi} F^{kl} h_{i;kl}^j &= \sigma \dot{\Phi} F^{kl} h_{rk} h_l^r h_i^j - \sigma \dot{\Phi} F h_{ri} h^{rj} + \sigma(\Phi - \tilde{f}) h_i^k h_k^j \\ &- \tilde{f}_{\alpha\beta} x_i^\alpha x_k^\beta g^{kj} + \sigma \tilde{f}_\alpha \nu^\alpha h_i^j - \tilde{f}_{\alpha\nu\beta} (x_i^\alpha x_k^\beta h^{kj} + x_l^\alpha x_k^\beta h_i^k g^{lj}) \\ &- \tilde{f}_{\nu^\alpha \nu^\beta} x_l^\alpha x_k^\beta h_i^k h^{lj} - \tilde{f}_{\nu^\beta} x_k^\beta h_{i;l}^k g^{lj} + \sigma \tilde{f}_{\nu^\alpha} \nu^\alpha h_i^k h_k^j \\ &+ \dot{\Phi} F^{kl,rs} h_{kl;i} h_{rs}^j + 2 \dot{\Phi} F^{kl} \bar{R}_{\alpha\beta\gamma\delta} x_m^\alpha x_i^\beta x_k^\gamma h_l^\delta g^{rj} \\ &- \dot{\Phi} F^{kl} \bar{R}_{\alpha\beta\gamma\delta} x_m^\alpha x_k^\beta x_r^\gamma h_i^\delta g^{rj} - \dot{\Phi} F^{kl} \bar{R}_{\alpha\beta\gamma\delta} x_m^\alpha x_k^\beta x_i^\gamma h_l^\delta h^{mj} \\ &+ \sigma \dot{\Phi} F^{kl} \bar{R}_{\alpha\beta\gamma\delta} \nu^\alpha x_k^\beta \nu^\gamma x_l^\delta h_i^j - \sigma \dot{\Phi} F \bar{R}_{\alpha\beta\gamma\delta} \nu^\alpha x_i^\beta \nu^\gamma x_m^\delta g^{mj} \\ &+ \sigma(\Phi - \tilde{f}) \bar{R}_{\alpha\beta\gamma\delta} \nu^\alpha x_i^\beta \nu^\gamma x_m^\delta g^{mj} + \dot{\Phi} F_i F^j \\ &+ \dot{\Phi} F^{kl} \bar{R}_{\alpha\beta\gamma\delta;\epsilon} \{ \nu^\alpha x_k^\beta x_l^\gamma x_i^\delta x_m^\epsilon g^{mj} + \nu^\alpha x_i^\beta x_k^\gamma x_m^\delta x_l^\epsilon g^{mj} \}. \end{aligned}$$

The proof is identical to that of Lemma 4.1; we only have to keep in mind that  $f$  now also depends on the normal.

If we had assumed  $F$  to be homogeneous of degree  $d_0$  instead of 1, then, we would have to replace the explicit term  $F$ —occurring twice in the preceding lemma—by  $d_0 F$ .

**4.9. Lemma** (Evolution of  $\tilde{v}$ ). *Consider the flow (3.7) in a Lorentzian space  $N$  such that the spacelike flow hypersurfaces can be written as graphs over  $\mathcal{S}_0$ . Then,  $\tilde{v}$  satisfies the evolution equation*

$$\begin{aligned}
 \dot{\tilde{v}} - \dot{\Phi} F^{ij} \tilde{v}_{ij} = & -\dot{\Phi} F^{ij} h_{ik} h_j^k \tilde{v} + [(\Phi - \tilde{f}) - \dot{\Phi} F] \eta_{\alpha\beta} \nu^\alpha \nu^\beta \\
 & - 2\dot{\Phi} F^{ij} h_j^k x_i^\alpha x_k^\beta \eta_{\alpha\beta} - \dot{\Phi} F^{ij} \eta_{\alpha\beta\gamma} x_i^\beta x_j^\gamma \nu^\alpha \\
 & - \dot{\Phi} F^{ij} \bar{R}_{\alpha\beta\gamma\delta} \nu^\alpha x_i^\beta x_j^\gamma \eta_\epsilon^\delta x_l^\epsilon g^{kl} \\
 & - \tilde{f}_\beta x_i^\beta x_k^\alpha \eta_\alpha g^{ik} - \tilde{f}_{\nu\beta} x_k^\beta h^{ik} x_i^\alpha \eta_\alpha,
 \end{aligned}
 \tag{4.37}$$

where  $\eta$  is the covariant vector field  $(\eta_\alpha) = e^\psi(-1, 0, \dots, 0)$ .

The proof is identical to the proof of Lemma 4.4.

In the Riemannian case we have:

**4.10. Lemma** (Evolution of  $v$ ). *Consider the flow (3.7) in a normal Gaussian coordinate system  $(x^\alpha)$ , where the  $M(t)$  can be written as graphs of a function  $u(t)$  over some compact Riemannian manifold  $\mathcal{S}_0$ . Then the quantity*

$$v = \sqrt{1 + |Du|^2} = (r_\alpha \nu^\alpha)^{-1} \tag{4.38}$$

satisfies the evolution equation

$$\begin{aligned}
 \dot{v} - \dot{\Phi} F^{ij} v_{ij} = & -\dot{\Phi} F^{ij} h_{ik} h_j^k v - 2v^{-1} \dot{\Phi} F^{ij} v_i v_j \\
 & + [(\Phi - f) - \dot{\Phi} F] r_{\alpha\beta} \nu^\alpha \nu^\beta v^2 \\
 & + 2\dot{\Phi} F^{ij} h_j^k x_i^\alpha x_k^\beta r_{\alpha\beta} v^2 + \dot{\Phi} F^{ij} r_{\alpha\beta\gamma} x_i^\beta x_j^\gamma \nu^\alpha v^2 \\
 & + \dot{\Phi} F^{ij} \bar{R}_{\alpha\beta\gamma\delta} \nu^\alpha x_i^\beta x_j^\gamma r_\epsilon^\delta x_l^\epsilon g^{kl} v^2 \\
 & + \tilde{f}_\beta x_i^\beta x_k^\alpha r_\alpha g^{ik} v^2 + \tilde{f}_{\nu\beta} x_k^\beta h^{ik} x_i^\alpha r_\alpha v^2,
 \end{aligned}
 \tag{4.39}$$

where  $r = x^0$  and  $(r_\alpha) = (1, 0, \dots, 0)$ .

## 5. STABILITY OF THE LIMIT HYPERSURFACES

**5.1. Definition.** Let  $N$  be semi-Riemannian,  $F$  a curvature operator, and  $M \subset N$  a compact, spacelike hypersurface, such that  $M$  is admissible and  $F^{ij}$ , evaluated at  $(h_{ij}, g_{ij})$ , the second fundamental form and metric of  $M$ , is divergence free, then  $M$  is said to be a *stable* solution of the equation

$$F|_M = f, \tag{5.1}$$

where  $f = f(x)$  is defined in a neighbourhood of  $M$ , if the first eigenvalue  $\lambda_1$  of the linearization, which is the operator in (3.33) on page 8, is non-negative, or equivalently, if the quadratic form

$$(5.2) \quad \int_M F^{ij} u_i u_j - \sigma \int_M \{F^{ij} h_i^k h_{kj} + F^{ij} \bar{R}_{\alpha\beta\gamma\delta} \nu^\alpha x_i^\beta \nu^\gamma x_j^\delta + f_\alpha \nu^\alpha\} u^2$$

is non-negative for all  $u \in C^2(M)$ .

It is well-known that the corresponding eigenspace is then onedimensional and spanned by a strictly positive eigenfunction  $\eta$

$$(5.3) \quad -F^{ij} \eta_{ij} - \sigma \{F^{ij} h_i^k h_{kj} + F^{ij} \bar{R}_{\alpha\beta\gamma\delta} \nu^\alpha x_i^\beta \nu^\gamma x_j^\delta + f_\alpha \nu^\alpha\} \eta = \lambda_1 \eta.$$

Notice that  $F^{ij}$  is supposed to be divergence free, which will be the case, if  $F = H_k$ ,  $1 \leq k \leq n$ , and the ambient space has constant curvature, as we shall prove at the end of this section. If  $k = 1$ , then  $F^{ij} = g^{ij}$  and  $N$  can be arbitrary, while in case  $k = 2$ , we have

$$(5.4) \quad F^{ij} = H g^{ij} - h^{ij},$$

hence  $N$  Einstein will suffice.

To simplify the formulation of the assumptions let us define:

**5.2. Definition.** A curvature function  $F$  is said to be of class  $(D)$ , if for every admissible hypersurface  $M$  the tensor  $F^{ij}$ , evaluated at  $M$ , is divergence free.

We shall prove in this section that the limit hypersurface of a converging curvature flow will be a stable stationary solution, if the initial flow velocity has a weak sign.

**5.3. Theorem.** *Suppose that the curvature flow (3.7) on page 5 exists for all time, and that the leaves  $M(t)$  converge in  $C^4$  to a hypersurface  $M$ , where the curvature function  $F$  is supposed to be of class  $(D)$ . Then  $M$  is a stable solution of the equation*

$$(5.5) \quad F|_M = f$$

*provided the velocity of the flow has a weak sign*

$$(5.6) \quad \Phi - \tilde{f} \geq 0 \quad \vee \quad \Phi - \tilde{f} \leq 0$$

*at  $t = 0$  and  $M(0)$  is not already a solution of (5.5).*

*Proof.* Convergence of a subsequence of the  $M(t)$  would actually suffice for the proof, however, the assumption (5.6) immediately implies that the flow converges, if a subsequence converges and a priori estimates in  $C^{4,\alpha}$  are valid.

The starting point is the evolution equation (3.20) on page 7 from which we deduce in view of the parabolic maximum principle that  $\Phi - \tilde{f}$  has a weak sign

during the evolution, cf. [18, Proposition 2.7.1], i.e., if we assume without loss of generality that at  $t = 0$

$$(5.7) \quad \Phi - \tilde{f} \geq 0,$$

then this inequality will be valid for all  $t$ . Moreover, there holds

$$(5.8) \quad \int_{M(t)} (\Phi - \tilde{f}) > 0 \quad \forall 0 \leq t < \infty$$

if this relation is valid for  $t = 0$ , as we shall prove in the lemma below.

On the other hand, the assumption

$$(5.9) \quad \int_{M(0)} (\Phi - \tilde{f}) > 0$$

is a natural assumption, for otherwise the initial hypersurface would already be a stationary solution which of course may not be stable.

Notice also that apart from the factor  $\dot{\Phi}$  the equation (3.20) looks like the parabolic version of the linearization of  $(F - f)$ . If the technical function  $\Phi = \Phi(r)$  is not the trivial one  $\Phi(r) = r$ , then we always assume that  $f > 0$  and that this is also valid for the limit hypersurface  $M$ . Only in case  $\Phi(r) = r$  and  $F = H$ , we allow  $f$  to be arbitrary.

Thus, our assumptions imply that in any case

$$(5.10) \quad \dot{\Phi} > \epsilon_0 > 0 \quad \forall t \in \mathbb{R}_+.$$

Furthermore, we derive from (3.20) that not only the elliptic part converges to 0 but also

$$(5.11) \quad (\Phi - \tilde{f})' = \dot{\Phi}\dot{F} + \sigma\dot{\Phi}(f)f_\alpha\nu^\alpha(\Phi - \tilde{f}),$$

i.e.,

$$(5.12) \quad \lim \dot{F} = 0.$$

Suppose now that  $M$  is not stable, then the first eigenvalue  $\lambda_1$  is negative and there exists a strictly positive eigenfunction  $\eta$  solving the equation (5.3) evaluated at  $M$ . Let  $\mathcal{U}$  be a tubular neighbourhood of  $M$  with a corresponding future directed normal Gaussian coordinate system  $(x^\alpha)$  and extend  $\eta$  to  $\mathcal{U}$  by setting

$$(5.13) \quad \eta(x^0, x) = \eta(x),$$

where, by a slight abuse of notation, we also denote  $(x^i)$  by  $x$ . Thus there holds

$$(5.14) \quad \eta_\alpha\nu^\alpha = 0$$

in  $M$ , and choosing  $\mathcal{U}$  sufficiently small, we may assume

$$(5.15) \quad |\eta_\alpha\nu^\alpha| < \eta$$

for all hypersurfaces  $M(t) \subset \mathcal{U}$ .

Now consider the term

$$(5.16) \quad \int_{M(t)} \dot{\Phi}^{-1}(\Phi - \tilde{f})\eta$$

for large  $t$ , which converges to 0. Since it is positive, in view of (5.8), there must exist a sequence of  $t$ , not explicitly labelled, tending to infinity such that

$$\begin{aligned}
 (5.17) \quad 0 &\geq \frac{d}{dt} \int_{M(t)} \dot{\Phi}^{-1}(\Phi - \tilde{f})\eta \\
 &= \int_{M(t)} -\dot{\Phi}^{-2} \ddot{\Phi} \dot{\Phi}(\Phi - \tilde{f})\eta + \int_{M(t)} \dot{\Phi}^{-1}(\Phi - \tilde{f})'\eta \\
 &\quad + \sigma \int_{M(t)} \dot{\Phi}^{-1} \eta_\alpha \nu^\alpha (\Phi - \tilde{f})^2 - 2\sigma \int_{M(t)} \dot{\Phi}^{-1}(\Phi - \tilde{f})^2 H\eta,
 \end{aligned}$$

where we used the relation (3.8) on page 5 to derive the last integral.

The rest of the proof is straight-forward. Multiply the equation (3.20) by  $\dot{\Phi}^{-1}\eta$  and integrate over  $M(t)$  for those values of  $t$  satisfying the preceding inequality to deduce

$$\begin{aligned}
 (5.18) \quad & - \int_{M(t)} \dot{\Phi}^{-1}(\Phi - \tilde{f})' = \int_{M(t)} -F^{ij} \eta_{ij}(\Phi - \tilde{f}) \\
 & - \sigma \int_{M(t)} \{F^{ij} h_i^k h_{kj} + F^{ij} \bar{R}_{\alpha\beta\gamma\delta} \nu^\alpha x_i^\beta \nu^\gamma x_j^\delta + \dot{\Phi}^{-1} \dot{\Phi}(f) f_\alpha \nu^\alpha\} \eta(\Phi - \tilde{f}),
 \end{aligned}$$

and conclude further that the right-hand side can be estimated from above by

$$(5.19) \quad \frac{\lambda_1}{2} \int_{M(t)} \eta(\Phi - \tilde{f})$$

for large  $t$ , while the left-hand side can be estimated from below by

$$(5.20) \quad -\epsilon(t) \int_{M(t)} (\Phi - \tilde{f})\eta$$

such that

$$(5.21) \quad \epsilon(t) > 0 \quad \wedge \quad \lim_{t \rightarrow \infty} \epsilon(t) = 0$$

in view of (5.17), where we used (5.12), (5.15) as well as

$$(5.22) \quad \lim_{t \rightarrow \infty} (\Phi - \tilde{f}) = 0;$$

a contradiction because of (5.8).  $\square$

**5.4. Lemma.** *Let  $M(t)$  be a solution of the curvature flow (3.7) on page 5 defined on a maximal time interval  $[0, T^*)$ ,  $0 < T^* \leq \infty$ , and suppose that  $\Phi - \tilde{f}$  has a weak sign at  $t = 0$ , e.g.,*

$$(5.23) \quad (\Phi - \tilde{f}) \geq 0$$

*and suppose furthermore that*

$$(5.24) \quad \int_{M(0)} (\Phi - \tilde{f}) > 0,$$

*then*

$$(5.25) \quad \int_{M(t)} (\Phi - \tilde{f}) > 0 \quad \forall 0 \leq t < T^*.$$

*Proof.* Let  $M_0$  be an abstract compact Riemannian manifold that is being isometrically embedded in  $N$  with image  $M(0)$ . Let  $(\xi^i)$  be a generic coordinate system for  $M_0$  and abbreviate  $(\Phi - \tilde{f})$  by  $u$ . The evolution equation (3.20) can then be looked at as a linear parabolic equation for  $u = u(t, \xi)$  on  $M_0$  with time dependent coefficients and time dependent Riemannian metric  $g_{ij}(t, \xi)$ .

By assumption  $u$  doesn't vanish identically at  $t = 0$ , i.e., there exists a ball  $B_\rho = B_\rho(\xi_0)$  such that

$$(5.26) \quad u(0, \xi) > 0 \quad \forall \xi \in \bar{B}_\rho(\xi_0).$$

Let  $\mathcal{C}$  be the cylinder

$$(5.27) \quad \mathcal{C} = [0, T^*) \times \bar{B}_\rho$$

and assume that there exists a first  $t_0 > 0$  such that

$$(5.28) \quad \inf_{\bar{B}_\rho} u(t_0, \cdot) = 0 = u(t_0, \xi_1).$$

We shall show that this is not possible: If  $\xi_1 \in B_\rho$ , then this contradicts the strong parabolic maximum principle, cf. [18, Lemma 2.7.1], and if  $\xi_1 \in \partial B_\rho$ , then we deduce from [18, Lemma 2.7.4] (a parabolic version of the Hopf Lemma)

$$(5.29) \quad \frac{\partial u}{\partial \nu}(t_0, \xi_1) < 0,$$

where  $\nu$  is the exterior normal of the ball  $B_\rho$  in  $\xi_1$ , contradicting the fact that the gradient of  $u(t_0, \cdot)$  vanishes in  $\xi_1$  because it is a minimum point; notice that we already know  $u \geq 0$  in  $[0, T^*) \times M_0$ .  $\square$

For some curvature operators one can prove a priori estimates for the second fundamental form only for stationary solutions and not for the leaves of a corresponding curvature flow. In order to use a curvature flow to obtain a stationary solution one uses „ $\epsilon$ -regularization“, i.e., instead of the curvature function  $F$  one considers

$$(5.30) \quad \tilde{F}(h_{ij}) = F(h_{ij} + \epsilon H g_{ij})$$

for  $\epsilon > 0$ , and starts a curvature flow with  $\tilde{F}$  and fixed  $\epsilon > 0$ .

A priori estimates for the regularized flow are usually fairly easily derived, since

$$(5.31) \quad \tilde{F}^{ij} = F^{ij} + \epsilon F^{kl} g_{kl} g^{ij},$$

but of course the estimates depend on  $\epsilon$ . Having uniform estimates one can deduce that the flow—or at least a subsequence—converges to a limit hypersurfaces  $M_\epsilon$  satisfying

$$(5.32) \quad \tilde{F}|_{M_\epsilon} = f.$$

Then, if uniform  $C^{4,\alpha}$ -estimates for the  $M_\epsilon$  can be derived, a subsequence will converge to a solution  $M$  of

$$(5.33) \quad F|_M = f,$$

cf. [13], where this method has been used to find hypersurfaces of prescribed scalar curvature in Lorentzian manifolds, see also Theorem 6.9 on page 36.

We shall now show that the solutions  $M$  obtained by this approach are all stable, if  $F$  is of class  $(D)$  and the initial velocities of the regularized flows have a weak sign. Notice that the curvature functions  $\tilde{F}$  are in general not of class  $(D)$ .

**5.5. Theorem.** *Let  $F$  be of class  $(D)$ , then any solution  $M$  of*

$$(5.34) \quad F|_M = f$$

*obtained by a regularized curvature flow as described above is stable, provided the initial velocity of the regularized flow has a weak sign, i.e., it satisfies*

$$(5.35) \quad \Phi - \tilde{f} \geq 0 \quad \vee \quad \Phi - \tilde{f} \leq 0$$

*at  $t = 0$  and the flow hypersurfaces converge to the stationary solution in  $C^4$ .*

*Proof.* Let  $M_\epsilon$  be the limit hypersurfaces of the regularized flow for  $\epsilon > 0$ , and assume that the  $M_\epsilon$  satisfy uniform  $C^{4,\alpha}$ -estimates such that a subsequence, not relabelled, converges in  $C^4$  to a compact spacelike hypersurface  $M$  solving the equation

$$(5.36) \quad F|_M = f.$$

Assume that  $M$  is not stable so that the first eigenvalue of the linearization is negative and there exists a strictly positive eigenfunction  $\eta$  satisfying (5.3). Extend  $\eta$  in a small tubular neighbourhood  $\mathcal{U}$  of  $M$  such that (5.15) is valid for all  $M_\epsilon$ , if  $\epsilon$  is small,  $\epsilon < \epsilon_0$ .

For those  $\epsilon$  we then deduce

$$(5.37) \quad \begin{aligned} & -\tilde{F}^{ij}\eta_{ij} - \tilde{F}_{;ij}^{ij}\eta - 2\tilde{F}_{;j}^{ij}\eta_i \\ & - \sigma\{\tilde{F}^{ij}h_i^k h_{kj} + \tilde{F}^{ij}\bar{R}_{\alpha\beta\gamma\delta}\nu^\alpha x_i^\beta \nu^\gamma x_j^\delta + f_\alpha \nu^\alpha\}\eta < \frac{\lambda_1}{2}\eta, \end{aligned}$$

where the inequality is evaluated at  $M_\epsilon$  and where we used the convergence in  $C^4$ .

Now, fix  $\epsilon$ ,  $\epsilon < \epsilon_0$ , then the preceding inequality is also valid for the flow hypersurfaces  $M(t)$  converging to  $M_\epsilon$ , if  $t$  is large, and the same arguments as at the end of the proof of Theorem 5.3 lead to a contradiction. Hence,  $M$  has to be a stable solution.  $\square$

Knowing that a solution is stable often allows to deduce further geometric properties of the underlying hypersurface like that it is either strictly stable or totally geodesic especially if the curvature function is the mean curvature, cf. e.g., [29], where the stability property has been extensively used to deduce geometric properties.

We want to prove that a neighbourhood of stable solutions can be foliated by a family of hypersurfaces satisfying the equation modulo a constant.

**5.6. Theorem.** *Let  $M \subset N$  be compact, spacelike, orientable and a stable solution of*

$$(5.38) \quad G|_M \equiv (F - f)|_M = 0,$$

*where  $F$  is of class  $(D)$  and  $M$  as well as  $F, f$  are of class  $C^{m,\alpha}$ ,  $2 \leq m \leq \infty$ ,  $0 < \alpha < 1$ , then a neighbourhood of  $M$  can be foliated by a family*

$$(5.39) \quad \Lambda = \{ M_\epsilon : |\epsilon| < \epsilon_0 \}$$

*of spacelike  $C^{m,\alpha}$ -hypersurfaces satisfying*

$$(5.40) \quad G|_{M_\epsilon} = \tau(\epsilon),$$

*where  $\tau$  is a real function of class  $C^{m,\alpha}$ . The  $M_\epsilon$  can be written as graphs over  $M$  in a tubular neighbourhood of  $M$*

$$(5.41) \quad M_\epsilon = \{ (u(\epsilon, x), x) : x \in M \}$$

*such that  $u$  is of class  $C^{m,\alpha}$  in both variables and there holds*

$$(5.42) \quad \dot{u} > 0.$$

*Proof.* (i) Let us assume that  $M$  is strictly stable. Consider a tubular neighbourhood of  $M$  with corresponding normal Gaussian coordinates  $(x^\alpha)$  such that  $M = \{x^0 = 0\}$ . The nonlinear operator  $G$  can then be viewed as an elliptic operator

$$(5.43) \quad G : B_\rho(0) \subset C^{m,\alpha}(M) \rightarrow C^{m-2,\alpha}(M)$$

where  $\rho$  is so small that all corresponding graphs are admissible.

In a smaller ball  $DG$  is a topological isomorphism, since  $M$  is strictly stable, and hence  $G$  is a diffeomorphism in a neighbourhood of the origin, and there exist smooth unique solutions

$$(5.44) \quad M_\epsilon = \{ u(\epsilon, x) : x \in M \} \quad |\epsilon| < \epsilon_0$$

of the equations

$$(5.45) \quad G|_{M_\epsilon} = \epsilon$$

such that  $u \in C^{m,\alpha}((-\epsilon_0, \epsilon_0) \times M)$ .

Differentiating with respect to  $\epsilon$  yields

$$(5.46) \quad DG\dot{u} = 1.$$

Let us consider this equation for  $\epsilon = 0$ , i.e., on  $M$ , and define

$$(5.47) \quad \eta = \min(\dot{u}, 0).$$

Then we deduce

$$(5.48) \quad 0 \leq \int_M \langle DG\eta, \eta \rangle = \int_M \eta \leq 0,$$

and hence there holds

$$(5.49) \quad \dot{u} \geq 0,$$

because of the strict stability of  $M$ .

Applying then the maximum principle to (5.46), we deduce further

$$(5.50) \quad \inf_M \dot{u} > 0,$$

hence the hypersurfaces form a foliation if  $\epsilon_0$  is chosen small enough such that

$$(5.51) \quad \inf_{M_\epsilon} \dot{u}(\epsilon, \cdot) > 0 \quad \forall |\epsilon| < \epsilon_0.$$

(ii) Assume now that  $M$  is not strictly stable. After introducing coordinates corresponding to a tubular neighbourhood  $\mathcal{U}$  of  $M$  as in part (i) any function  $u \in C^{m,\alpha}(M)$  with  $|u|_{m,\alpha}$  small enough defines an admissible hypersurface

$$(5.52) \quad M(u) = \text{graph } u \subset \mathcal{U}$$

such that  $G|_{M(u)}$  can be expressed as

$$(5.53) \quad G|_{M(u)} = G(u).$$

Let

$$(5.54) \quad A = DG(0),$$

then  $A$  is self-adjoint, monotone

$$(5.55) \quad \langle Au, u \rangle \geq 0 \quad \forall u \in H^{1,2}(M)$$

and the smallest eigenvalue of  $A$  is equal to zero, the corresponding eigenspace spanned by a strictly positive eigenfunction  $\eta$ .

Similarly as in [2, p. 621] we consider the operator

$$(5.56) \quad \Psi(u, \tau) = (G(u) - \tau, \varphi(u))$$

defined in  $B_\rho(0) \times \mathbb{R}$ ,  $B_\rho(0) \subset C^{m,\alpha}(M)$  for small  $\rho > 0$ , where  $\varphi$  is a linear functional

$$(5.57) \quad \varphi(u) = \int_M \eta u$$

$\Psi$  is of class  $C^{m,\alpha}$  and maps

$$(5.58) \quad \Psi : B_\rho(0) \times \mathbb{R} \rightarrow C^{m-2,\alpha}(M) \times \mathbb{R},$$

such that

$$(5.59) \quad D\Psi = \begin{pmatrix} DG & -1 \\ \varphi & 0 \end{pmatrix}$$

evaluated at  $(0, 0)$  is bijective as one easily checks. Indeed let  $(u, \epsilon)$  satisfy

$$(5.60) \quad D\Psi(u, \epsilon) = (0, 0),$$

then

$$(5.61) \quad Au = DG u = \epsilon \quad \wedge \quad \int_M \eta u = 0,$$

hence

$$(5.62) \quad \epsilon \int_M \eta = \langle Au, \eta \rangle = \langle u, A\eta \rangle = 0$$

and we conclude  $\epsilon = 0$  as well as  $u = 0$ .

To prove the surjectivity, let  $(w, \delta) \in C^{m-2, \alpha}(M) \times \mathbb{R}$  be arbitrary. Choosing

$$(5.63) \quad \epsilon = -\frac{\int_M w \eta}{\int_M \eta}$$

we deduce

$$(5.64) \quad \int_M (\epsilon + w) \eta = 0,$$

hence there exists  $\bar{u} \in C^{m, \alpha}(M)$  solving

$$(5.65) \quad A\bar{u} = \epsilon + w$$

and

$$(5.66) \quad u = \bar{u} + \lambda \eta$$

with

$$(5.67) \quad \lambda = \delta - \int_M \eta \bar{u}$$

then satisfies

$$(5.68) \quad \int_M \eta u = \epsilon,$$

i.e.,

$$(5.69) \quad D\Psi(u, \epsilon) = (w, \delta).$$

Applying the inverse function theorem we conclude that there exists  $\epsilon_0 > 0$  and functions  $(u(\epsilon, x), \tau(\epsilon))$  of class  $C^{m, \alpha}$  in both variables such that

$$(5.70) \quad G(u(\epsilon)) = \tau(\epsilon) \quad \wedge \quad \int_M \eta u(\epsilon) = \epsilon \quad \forall |\epsilon| < \epsilon_0;$$

$\tau(\epsilon)$  is constant for fixed  $\epsilon$ .

The hypersurfaces

$$(5.71) \quad \Lambda = \{ M_\epsilon = M(u(\epsilon)) : |\epsilon| < \epsilon_0 \}$$

will form a foliation, if we can show that

$$(5.72) \quad \dot{u} \neq 0.$$

Differentiating the equations in (5.70) with respect to  $\epsilon$  and evaluating the result at  $\epsilon = 0$  yields

$$(5.73) \quad A\dot{u}(0) = \dot{\tau}(0) \quad \wedge \quad \int_M \eta \dot{u}(0) = 1$$

and we deduce further

$$(5.74) \quad \dot{\tau}(0) \int_M \eta = \langle A\dot{u}(0), \eta \rangle = \langle \dot{u}(0), A\eta \rangle = 0$$

and thus

$$(5.75) \quad \dot{\tau}(0) = 0 \quad \wedge \quad \dot{u}(0) = \eta > 0,$$

if  $\eta$  is normalized such that  $\langle \eta, \eta \rangle = 1$ , i.e., we have  $\dot{u}(\epsilon) > 0$ , if  $\epsilon_0$  is chosen small enough.  $\square$

**5.7. Remark.** Let  $M$  be a stable solution of

$$(5.76) \quad G|_M = 0$$

as in the preceding theorem, but not strictly stable and let  $M_\epsilon$  be a foliation of a neighbourhood of  $M$  such that

$$(5.77) \quad G|_{M_\epsilon} = \tau(\epsilon) \quad \forall |\epsilon| < \epsilon_0.$$

If  $M$  is the limit hypersurface of a curvature flow as in Theorem 5.3, then

$$(5.78) \quad \tau(\epsilon) > 0 \quad \forall 0 < \epsilon < \epsilon_0,$$

if the flow hypersurfaces  $M(t)$  converge to  $M$  from above, which is tantamount to

$$(5.79) \quad \Phi(F) - \tilde{f} \geq 0,$$

or we have

$$(5.80) \quad \tau(\epsilon) < 0 \quad \forall -\epsilon_0 < \epsilon < 0,$$

if

$$(5.81) \quad \Phi(F) - \tilde{f} \leq 0,$$

in which case the flow hypersurfaces converge to  $M$  from below.

The direction „above“ is defined by the region the normal  $\sigma\nu$  of  $M$  points to.

*Proof.* Let us assume that the flow hypersurfaces satisfy (5.79) and fix  $0 < \epsilon < \epsilon_0$ . We may also suppose that the initial hypersurface  $M(0)$  doesn't intersect the tubular neighbourhood of  $M$  which is being foliated by  $M_\epsilon$ . Now, fix  $0 < \epsilon < \epsilon_0$ , then there must be a first  $t > 0$  such that  $M(t)$  touches  $M_\epsilon$  from above which yields, in view of the maximum principle,

$$(5.82) \quad G|_{M_\epsilon} = \tau(\epsilon) > 0,$$

since  $\tau(\epsilon) \leq 0$  would imply  $\tau(\epsilon) = 0$  and  $M_\epsilon = M(t)$ , cf. [18, Theorem 2.7.9], i.e.,  $M(t)$  would be a stationary solution, which is impossible as we have proved in Lemma 5.4.  $\square$

Finally, let us show that the symmetric polynomials  $H_k$ ,  $1 \leq k \leq n$ , are of class  $(D)$ , if the ambient space has constant curvature.

**5.8. Lemma.** *Let  $N$  be a semi-Riemannian space of constant curvature, then the symmetric polynomials  $F = H_k$ ,  $1 \leq k \leq n$ , are of class  $(D)$ . In case  $k = 2$  it suffices to assume  $N$  Einstein.*

*Proof.* We shall prove the result by induction on  $k$ . First we note that the cones of definition  $\Gamma_k \subset \mathbb{R}^n$  of the  $H_k$  form an ordered chain

$$(5.83) \quad \Gamma_k \subset \Gamma_{k-1} \quad \forall 1 < k \leq n,$$

cf. [7], so that a hypersurface admissible for  $H_k$  is also admissible for  $H_{k-1}$ .

For  $k = 1$  we have

$$(5.84) \quad F^{ij} = g^{ij}$$

and the result is obviously valid for arbitrary  $N$ .

Thus let us assume that the result is already proved for  $1 \leq k < n$ . Set  $F = H_{k+1}$ ,  $\hat{F} = H_k$  and let  $M$  be an admissible hypersurface for  $F$  with principal curvatures  $\kappa_i$ .

From the definition of the  $H_k$ 's we immediately deduce

$$(5.85) \quad \hat{F} = \frac{\partial F}{\partial \kappa_i} + \kappa_i \frac{\partial \hat{F}}{\partial \kappa_i}$$

for fixed  $i$ , no summation over  $i$ , or equivalently,

$$(5.86) \quad \hat{F} g^{ij} = F^{ij} + \hat{F}^{jm} h_m^i,$$

notice that the last term is a symmetric tensor, since for any symmetric curvature function  $F$   $F^{ij}$  and  $h_{ij}$  commute, cf. [18, Lemma 2.1.9]. Thus there holds

$$(5.87) \quad F^{ij} = \hat{F} g^{ij} - \hat{F}^{jm} h_m^i$$

and we deduce, using the induction hypothesis,

$$(5.88) \quad \begin{aligned} F^{ij}_{;j} &= \hat{F}^i - \hat{F}^{jm} h_{m;j}^i = \hat{F}^i - \hat{F}^{jm} h_{mj}^i{}_{;i} \\ &= \hat{F}^i - \hat{F}^i = 0, \end{aligned}$$

where we applied the Codazzi equations at one point.

If  $F = H_2$ , then

$$(5.89) \quad F^{ij} = H g^{ij} - h^{ij}$$

and the assumption  $N$  Einstein suffices to conclude that  $F^{ij}$  is divergence free.  $\square$

## 6. EXISTENCE RESULTS

From now we shall assume that ambient manifold  $N$  is Lorentzian, or more precisely, that it is smooth, globally hyperbolic with a compact, connected Cauchy hypersurface. Then there exists a smooth future oriented time function  $x^0$  such that the metric in  $N$  can be expressed in Gaussian coordinates  $(x^\alpha)$  as

$$(6.1) \quad d\bar{s}^2 = e^{2\psi} \{-(dx^0)^2 + \sigma_{ij} dx^i dx^j\},$$

where  $x^0$  is the time function and the  $(x^i)$  are local coordinates for

$$(6.2) \quad \mathcal{S}_0 = \{x^0 = 0\}.$$

$\mathcal{S}_0$  is then also a compact, connected Cauchy hypersurface. For a proof of the splitting result see [4, Theorem 1.1], and for the fact that all Cauchy hypersurfaces are diffeomorphic and hence  $\mathcal{S}_0$  is also compact and connected, see [3, Lemma 2.2].

One advantage of working in globally hyperbolic spacetimes with a compact Cauchy hypersurface is that all compact, connected spacelike  $C^m$ -hypersurfaces  $M$  can be written as graphs over  $\mathcal{S}_0$ .

**6.1. Lemma.** *Let  $N$  be as above and  $M \subset N$  a connected, spacelike hypersurface of class  $C^m$ ,  $1 \leq m$ , then  $M$  can be written as a graph over  $\mathcal{S}_0$*

$$(6.3) \quad M = \text{graph } u|_{\mathcal{S}_0}$$

with  $u \in C^m(\mathcal{S}_0)$ .

We proved this lemma under the additional hypothesis that  $M$  is achronal, [10, Proposition 2.5], however, this assumption is unnecessary as has been shown in [25, Theorem 1.1].

We are looking at the curvature flow (3.7) on page 5 and want to prove that it converges to a stationary solution hypersurface, if certain assumptions are satisfied.

The existence proof consists of four steps:

- (i) Existence on a maximal time interval  $[0, T^*)$ .
- (ii) Proof that the flow stays in a compact subset.
- (iii) Uniform a priori estimates in an appropriate function space, e.g.,  $C^{4,\alpha}(\mathcal{S}_0)$  or  $C^\infty(\mathcal{S}_0)$ , which, together with (ii), would imply  $T^* = \infty$ .
- (iv) Conclusion that the flow—or at least a subsequence of the flow hypersurfaces—converges if  $t$  tends to infinity.

The existence on a maximal time interval is always guaranteed, if the data are sufficiently regular, since the problem is parabolic. If the flow hypersurfaces can be written as graphs in a Gaussian coordinate system, as will always be the case in a globally hyperbolic spacetime with a compact Cauchy hypersurface in view of Lemma 6.1, the conditions are better than in the general case:

**6.2. Theorem.** *Let  $4 \leq m \in \mathbb{N}$  and  $0 < \alpha < 1$ , and assume the semi-Riemannian space  $N$  to be of class  $C^{m+2,\alpha}$ . Let the strictly monotone curvature function  $F$ , the functions  $f$  and  $\Phi$  be of class  $C^{m,\alpha}$  and let  $M_0 \in C^{m+2,\alpha}$  be an admissible compact, spacelike, connected, orientable<sup>3</sup> hypersurface. Then the curvature flow (3.7) on page 5 with initial hypersurface  $M_0$  exists in a maximal time interval  $[0, T^*)$ ,  $0 < T^* \leq \infty$ , where in case that the flow hypersurfaces cannot be expressed as graphs they are supposed to be smooth, i.e., the conditions should be valid for arbitrary  $4 \leq m \in \mathbb{N}$  in this case.*

---

<sup>3</sup>Recall that oriented simply means there exists a continuous normal, which will always be the case in a globally hyperbolic spacetime.

A proof can be found in [18, Theorem 2.5.19, Lemma 2.6.1].

The second step, that the flow stays in a compact set, can only be achieved by barrier assumptions, cf. Definition 2.1. Thus, let  $\Omega \subset N$  be open and precompact such that  $\partial\Omega$  has exactly two components

$$(6.4) \quad \partial\Omega = M_1 \dot{\cup} M_2$$

where  $M_1$  is a lower barrier for the pair  $(F, f)$  and  $M_2$  an upper barrier. Moreover,  $M_1$  has to lie in the past of  $M_2$

$$(6.5) \quad M_1 \subset I^-(M_2),$$

cf. [18, Remark 2.7.8].

Then the flow hypersurfaces will always stay inside  $\bar{\Omega}$ , if the initial hypersurface  $M_0$  satisfies  $M_0 \subset \Omega$ , [18, Theorem 2.7.9]. This result is also valid if  $M_0$  coincides with one the barriers, since then the velocity  $(\Phi - \tilde{f})$  has a weak sign and the flow moves into  $\Omega$  for small  $t$ , if it moves at all, and the arguments of the proof are applicable.

In Lorentzian manifolds the existence of barriers is associated with the presence of past and future singularities. In globally hyperbolic spacetimes, when  $N$  is topologically a product

$$(6.6) \quad N = I \times \mathcal{S}_0,$$

where  $I = (a, b)$ , singularities can only occur, when the endpoints of the interval are approached. A singularity, if one exists, is called a *crushing singularity*, if the sectional curvatures become unbounded, i.e.,

$$(6.7) \quad \bar{R}_{\alpha\beta\gamma\delta} \bar{R}^{\alpha\beta\gamma\delta} \rightarrow \infty$$

and such a singularity should provide a future resp. past barrier for the mean curvature function  $H$ .

**6.3. Definition.** Let  $N$  be a globally hyperbolic spacetime with compact Cauchy hypersurface  $\mathcal{S}_0$  so that  $N$  can be written as a topological product  $N = I \times \mathcal{S}_0$  and its metric expressed as

$$(6.8) \quad d\bar{s}^2 = e^{2\psi}(-(dx^0)^2 + \sigma_{ij}(x^0, x)dx^i dx^j).$$

Here,  $x^0$  is a globally defined future directed time function and  $(x^i)$  are local coordinates for  $\mathcal{S}_0$ .  $N$  is said to have a *future* resp. *past mean curvature barrier*, if there are sequences  $M_k^+$  resp.  $M_k^-$  of closed, spacelike, admissible hypersurfaces such that

$$(6.9) \quad \lim_{k \rightarrow \infty} H|_{M_k^+} = \infty \quad \text{resp.} \quad \lim_{k \rightarrow \infty} H|_{M_k^-} = -\infty$$

and

$$(6.10) \quad \limsup \inf_{M_k^+} x^0 > x^0(p) \quad \forall p \in N$$

resp.

$$(6.11) \quad \liminf_{M_k^-} \sup x^0 < x^0(p) \quad \forall p \in N,$$

If one stipulates that the principal curvatures of the  $M_k^+$  resp.  $M_k^-$  tend to plus resp. minus infinity, then these hypersurfaces could also serve as barriers for other curvature functions. The past barriers would most certainly be non-admissible for any curvature function except  $H$ .

**6.4. Remark.** Notice that the assumptions (6.9) alone already implies (6.10) resp. (6.11), if either

$$(6.12) \quad \limsup_{M_k^+} \inf x^0 > a$$

resp.

$$(6.13) \quad \liminf_{M_k^-} \sup x^0 < b$$

where  $(a, b) = x^0(N)$ , or, if

$$(6.14) \quad \bar{R}_{\alpha\beta} \nu^\alpha \nu^\beta \geq -\Lambda \quad \forall \langle \nu, \nu \rangle = -1.$$

where  $\Lambda \geq 0$ .

*Proof.* It suffices to prove that the relation (6.10) is automatically satisfied under the assumptions (6.12) or (6.14) by switching the light cone and replacing  $x^0$  by  $-x^0$  in case of the past barrier.

Fix  $k$ , and let

$$(6.15) \quad \tau_k = \inf_{M_k} x^0,$$

then the coordinate slice

$$(6.16) \quad M_{\tau_k} = \{x^0 = \tau_k\}$$

touches  $M_k$  from below in a point  $p_k \in M_k$  where  $\tau_k = x^0(p_k)$  and the maximum principle yields that in that point

$$(6.17) \quad H|_{M_{\tau_k}} \geq H|_{M_k},$$

hence, if  $k$  tends to infinity the points  $(p_k)$  cannot stay in a compact subset, i.e.,

$$(6.18) \quad \limsup x^0(p_k) \rightarrow b$$

or

$$(6.19) \quad \limsup x^0(p_k) \rightarrow a.$$

We shall show that only (6.18) can be valid. The relation (6.19) evidently contradicts (6.12).

In case the assumption (6.14) is valid, we consider a fixed coordinate slice  $M_0 = \{x^0 = \text{const}\}$ , then all hypersurfaces  $M_k$  satisfying

$$(6.20) \quad H|_{M_0} < \inf_{M_k} H \quad \wedge \quad \sqrt{n\Lambda} < \inf_{M_k} H$$

have to lie in the future of  $M_0$ , cf. [18, Lemma 4.7.1], hence the result.  $\square$

A future mean curvature barrier certainly represents a singularity, at least if  $N$  satisfies the condition

$$(6.21) \quad \bar{R}_{\alpha\beta}\nu^\alpha\nu^\beta \geq -\Lambda \quad \forall \langle \nu, \nu \rangle = -1$$

where  $\Lambda \geq 0$ , because of the future timelike incompleteness, which is proved in [1], and is a generalization of Hawking's earlier result for  $\Lambda = 0$ , [24]. But these singularities need not be crushing, cf. [15, Section 2] for a counterexample.

The uniform a priori estimates for the flow hypersurfaces are the hardest part in any existence proof. When the flow hypersurfaces can be written as graphs it suffices to prove  $C^1$  and  $C^2$  estimates, namely, the induced metric

$$(6.22) \quad g_{ij}(t, \xi) = \langle x_i, x_j \rangle$$

where  $x = x(t, \xi)$  is a local embedding of the flow, should stay uniformly positive definite, i.e., there should exist positive constants  $c_i$ ,  $1 \leq i \leq 2$ , such that

$$(6.23) \quad c_1 g_{ij}(0, \xi) \leq g_{ij}(t, \xi) \leq c_2 g_{ij}(0, \xi),$$

or equivalently, that the quantity

$$(6.24) \quad \tilde{v} = \langle \eta, \nu \rangle,$$

where  $\nu$  is the past directed normal of  $M(t)$  and  $\eta$  the vector field

$$(6.25) \quad \eta = (\eta_\alpha) = e^\psi(-1, 0, \dots, 0),$$

is uniformly bounded, which is achieved with the help of the parabolic equation (4.37) on page 15, if it is possible at all.

However, in some special situations  $C^1$ -estimates are automatically satisfied, cf. Theorem 6.11 at the end of this section.

For the  $C^2$ -estimates the principle curvatures  $\kappa_i$  of the flow hypersurfaces have to stay in a compact set in the cone of definition  $\Gamma$  of  $F$ , e.g., if  $F$  is the Gaussian curvature, then  $\Gamma = \Gamma_+$  and one has to prove that there are positive constants  $k_i$ ,  $i = 1, 2$  such that

$$(6.26) \quad k_1 \leq \kappa_i \leq k_2 \quad \forall 1 \leq i \leq n$$

uniformly in the cylinder  $[0, T^*) \times M_0$ , where  $M_0$  is any manifold that can serve as a base manifold for the embedding  $x = x(t, \xi)$ .

The parabolic equations that are used for these curvature estimates are (4.36) on page 14, usually for an upper estimate, and (4.33) on page 14 for the lower estimate. Indeed, suppose that the flow starts at the upper barrier, then

$$(6.27) \quad F \geq f$$

at  $t = 0$  and this estimate remains valid throughout the evolution because of the parabolic maximum principle, use (4.36). Then, if upper estimates for the  $\kappa_i$  have been derived and if  $f > 0$  uniformly, then we conclude from (6.27) that the  $\kappa_i$  stay in a compact set inside the open cone  $\Gamma$ , since

$$(6.28) \quad F|_{\partial\Gamma} = 0.$$

To obtain higher order estimates we are going to exploit the fact that the flow hypersurfaces are graphs over  $\mathcal{S}_0$  in an essential way, namely, we look at the associated scalar flow equation (4.21) on page 12 satisfied by  $u$ . This equation is a nonlinear uniformly parabolic equation, where the operator  $\Phi(F)$  is also concave in  $h_{ij}$ , or equivalently, convex in  $u_{ij}$ , i.e., the  $C^{2,\alpha}$ -estimates of Krylov and Safonov, [26, Chapter 5.5] or see [28, Chapter 10.6] for a very clear and readable presentation, are applicable, yielding uniform estimates for the standard parabolic Hölder semi-norm

$$(6.29) \quad [D^2u]_{\beta, \bar{Q}_T}$$

for some  $0 < \beta \leq \alpha$  in the cylinder

$$(6.30) \quad Q = [0, T) \times \mathcal{S}_0,$$

independent of  $0 < T < T^*$ , which in turn will lead to  $H^{m+2+\alpha, \frac{m+2+\alpha}{2}}(\bar{Q}_T)$  estimates, cf. [18, Theorem 2.5.9, Remark 2.6.2].

$H^{m+2+\alpha, \frac{m+2+\alpha}{2}}(\bar{Q}_T)$  is a parabolic Hölder space, cf. [27, p. 7] for the original definition and [18, Note 2.5.4] in the present context.

The estimate (6.29) combined with the uniform  $C^2$ -norm leads to uniform  $C^{2,\beta}(\mathcal{S}_0)$ -estimates independent of  $T$ .

These estimates imply that  $T^* = \infty$ .

Thus, it remains to prove that  $u(t, \cdot)$  converges in  $C^{m+2}(\mathcal{S}_0)$  to a stationary solution  $\tilde{u}$ , which is then also of class  $C^{m+2,\alpha}(\mathcal{S}_0)$  in view of the Schauder theory.

Because of the preceding a priori estimates  $u(t, \cdot)$  is precompact in  $C^2(\mathcal{S}_0)$ . Moreover, we deduce from the scalar flow equation (4.21) on page 12 that  $\dot{u}$  has a sign, i.e., the  $u(t, \cdot)$  converge monotonely in  $C^0(\mathcal{S}_0)$  to  $\tilde{u}$  and therefore also in  $C^2(\mathcal{S}_0)$ .

To prove that graph  $\tilde{u}$  is a solution, we again look at (4.21) and integrate it with respect to  $t$  to obtain for fixed  $x \in \mathcal{S}_0$

$$(6.31) \quad |\tilde{u}(x) - u(t, x)| = \int_t^\infty e^{-\psi} v |\Phi - \tilde{f}|,$$

where we used that  $(\Phi - \tilde{f})$  has a sign, hence  $(\Phi - \tilde{f})(t, x)$  has to vanish when  $t$  tends to infinity, at least for a subsequence, but this suffices to conclude that graph  $\tilde{u}$  is a stationary solution and

$$(6.32) \quad \lim_{t \rightarrow \infty} (\Phi - \tilde{f}) = 0.$$

Using the convergence of  $u$  to  $\tilde{u}$  in  $C^2$ , we can then prove:

**6.5. Theorem.** *The functions  $u(t, \cdot)$  converge in  $C^{m+2}(\mathcal{S}_0)$  to  $\tilde{u}$ , if the data satisfy the assumptions in Theorem 6.2, since we have*

$$(6.33) \quad u \in H^{m+2+\beta, \frac{m+2+\beta}{2}}(\bar{Q}),$$

where  $Q = Q_\infty$ .

*Proof.* Out of convention let us write  $\alpha$  instead of  $\beta$  knowing that  $\alpha$  is the Hölder exponent in (6.29).

We shall reduce the Schauder estimates to the standard Schauder estimates in  $\mathbb{R}^n$  for the heat equation with a right-hand side by using the already established results (6.29) and

$$(6.34) \quad u(t, \cdot) \xrightarrow{C^2(\mathcal{S}_0)} \tilde{u} \in C^{m+2, \alpha}(\mathcal{S}_0).$$

Let  $(U_k)$  be a finite open covering of  $\mathcal{S}_0$  such that each  $U_k$  is contained in a coordinate chart and

$$(6.35) \quad \text{diam } U_k < \rho,$$

$\rho$  small,  $\rho$  will be specified in the proof, and let  $(\eta_k)$  be a subordinate finite partition of unity of class  $C^{m+2, \alpha}$ .

Since

$$(6.36) \quad u \in H^{m+2+\alpha, \frac{m+2+\alpha}{2}}(\bar{Q}_T)$$

for any finite  $T$ , cf. [18, Lemma 2.6.1], and hence

$$(6.37) \quad u(t, \cdot) \in C^{m+2, \alpha}(\mathcal{S}_0) \quad \forall 0 \leq t < \infty$$

we shall choose  $u_0 = u(t_0, \cdot)$  as initial value for some large  $t_0$  such that

$$(6.38) \quad |a^{ij}(t, \cdot) - \tilde{a}^{ij}|_{0, \mathcal{S}_0} < \epsilon/2 \quad \forall t \geq t_0,$$

where

$$(6.39) \quad a^{ij} = v^2 \dot{\Phi} F^{ij}$$

and  $\tilde{a}^{ij}$  is defined correspondingly for  $\tilde{M} = \text{graph } \tilde{u}$ .

However, making a variable transformation we shall always assume that  $t_0 = 0$  and  $u_0 = u(0, \cdot)$ .

We shall prove (6.33) successively.

(i) Let us first show that

$$(6.40) \quad D_x u \in H^{2+\alpha, \frac{2+\alpha}{2}}(\bar{Q}).$$

This will be achieved, if we show that for an arbitrary  $\xi \in C^{m+1, \alpha}(T^{1,0}(\mathcal{S}_0))$

$$(6.41) \quad \varphi = D_\xi u \in H^{2+\alpha, \frac{2+\alpha}{2}}(\bar{Q}),$$

cf. [18, Remark 2.5.11].

Differentiating the scalar flow equation (4.21) on page 12 with respect to  $\xi$  we obtain

$$(6.42) \quad \dot{\varphi} - a^{ij} \varphi_{ij} + b^i \varphi_i + c \varphi = f,$$

where of course the symbol  $f$  has a different meaning then in (4.21).

Later we want to apply the Schauder estimates for solutions of the heat flow equation with right-hand side. In order to use elementary potential estimates we have to cut off  $\varphi$  near the origin  $t = 0$  by considering

$$(6.43) \quad \tilde{\varphi} = \varphi\theta,$$

where  $\theta = \theta(t)$  is smooth satisfying

$$(6.44) \quad \theta(t) = \begin{cases} 1, & t > 1, \\ 0, & t \leq \frac{1}{2}. \end{cases}$$

This modification doesn't cause any problems, since we already have a priori estimates for finite  $t$ , and we are only concerned about the range  $1 \leq t < \infty$ .  $\tilde{\varphi}$  satisfies the same equation as  $\varphi$  only the right-hand side has the additional summand  $w\dot{\theta}$ .

Let  $\eta = \eta_k$  be one of the members of the partition of unity and set

$$(6.45) \quad w = \tilde{\varphi}\eta,$$

then  $w$  satisfies a similar equation with slightly different right-hand side

$$(6.46) \quad \dot{w} - a^{ij}w_{ij} + b^i w_i + cw = \tilde{f}$$

but we shall have this in mind when applying the estimates.

The  $w(t, \cdot)$  have compact support in one of the  $U_k$ 's, hence we can replace the covariant derivatives of  $w$  by ordinary partial derivatives without changing the structure of the equation and the properties of the right-hand side, which still only depends linearly on  $\varphi$  and  $D\varphi$ .

We want to apply the well-known estimates for the ordinary heat flow equation

$$(6.47) \quad \dot{w} - \Delta w = \hat{f}$$

where  $w$  is defined in  $\mathbb{R} \times \mathbb{R}^n$ .

To reduce the problem to this special form, we pick an arbitrary  $x_0 \in U_k$ , set  $z_0 = (0, x_0)$ ,  $z = (t, x)$  and consider instead of (6.46)

$$(6.48) \quad \begin{aligned} \dot{w} - a^{ij}(z_0)w_{ij} &= \hat{f} \\ &= [a^{ij}(z) - a^{ij}(z_0)]w_{ij} - b^i w_i - cw + \tilde{f}, \end{aligned}$$

where we emphasize that the difference

$$(6.49) \quad |a^{ij}(z) - a^{ij}(z_0)|$$

can be made smaller than any given  $\epsilon > 0$  by choosing  $\rho = \rho(\epsilon)$  in (6.35) and  $t_0 = t_0(\epsilon)$  in (6.38) accordingly. Notice also that this equation can be extended into  $\mathbb{R} \times \mathbb{R}^n$ , since all functions have support in  $\{t \geq \frac{1}{2}\}$ .

Let  $0 < T < \infty$  be arbitrary, then all terms belong to the required function spaces in  $\bar{Q}_T$  and there holds

$$(6.50) \quad [w]_{2+\alpha, Q_T} \leq c[\hat{f}]_{\alpha, Q_T},$$

where  $c = c(n, \alpha)$ . The brackets indicate the standard unweighted parabolic semi-norms, cf. [18, Definition 2.5.2], which are identical to those defined in [27, p. 7], but there the brackets are replaced by kets.

Thus, we conclude

$$(6.51) \quad \begin{aligned} [w]_{2+\alpha, Q_T} &\leq c \sup_{U_k \times (0, T)} |a^{ij}(z) - a^{ij}(z_0)| [D^2 w]_{\alpha, Q_T} + c[f]_{\alpha, Q_T} \\ &\quad + c_1 \{ [D^2 u]_{\alpha, Q_+} + [Du]_{\alpha, Q_T} + [u]_{\alpha, Q_T} + |w|_{0, Q_T} + |D^2 w|_{0, Q_T} \}, \end{aligned}$$

where  $c_1$  is independent of  $T$ , but dependent on  $\eta_k$ . Here we also used the fact that the lower order coefficients and  $\varphi, D\varphi$  are uniformly bounded.

Choosing now  $\epsilon > 0$  so small that

$$(6.52) \quad c\epsilon < \frac{1}{2}$$

and  $\rho, t_0$  accordingly such the difference in (6.49) is smaller than  $\epsilon$ , we deduce

$$(6.53) \quad \begin{aligned} [w]_{2+\alpha, Q_T} &\leq 2c[f]_{\alpha, Q_T} \\ &\quad + 2c_1 \{ [D^2 u]_{\alpha, Q_+} + [Du]_{\alpha, Q_T} + [u]_{\alpha, Q_T} + |w|_{0, Q_T} + |D^2 w|_{0, Q_T} \}, \end{aligned}$$

Summing over the partition of unity and noting that  $\xi$  is arbitrary we see that in the preceding inequality we can replace  $w$  by  $Du$  everywhere resulting in the estimate

$$(6.54) \quad \begin{aligned} [Du]_{2+\alpha, Q_T} &\leq c_1 [f]_{\alpha, Q_T} \\ &\quad + c_1 \{ [D^2 u]_{\alpha, Q_+} + [Du]_{\alpha, Q_T} + [u]_{\alpha, Q_T} + |Du|_{0, Q_T} + |D^3 u|_{0, Q_T} \} \end{aligned}$$

where  $c_1$  is a new constant still independent of  $T$ .

Now the only critical terms on the right-hand side are  $|D^3 u|_{0, Q_T}$ , which can be estimated by (6.57), and the Hölder semi-norms with respect to  $t$

$$(6.55) \quad [Du]_{\frac{\alpha}{2}, t, Q_T} + [u]_{\frac{\alpha}{2}, t, Q_T}.$$

The second one is taken care of by the boundedness of  $\dot{u}$ , see (4.21) on page 12, while the first one is estimated with the help of equation (6.42) revealing

$$(6.56) \quad |D\dot{u}| \leq c \left\{ \sup_{[0, T]} |u|_{3, S_0} + |f|_{0, Q_T} \right\},$$

since for fixed but arbitrary  $t$  we have

$$(6.57) \quad |u|_{3, S_0} \leq \epsilon [D^3 u]_{\alpha, S_0} + c_\epsilon |u|_{0, S_0},$$

where  $c_\epsilon$  is independent of  $t$ .

Hence we conclude

$$(6.58) \quad |Du|_{2+\alpha, Q_T} \leq \text{const}$$

uniformly in  $T$ .

(ii) Repeating these estimates successively for  $2 \leq l \leq m$  we obtain uniform estimates for

$$(6.59) \quad \sum_{l=2}^m [D_x^l u]_{2+\alpha, Q_T},$$

which, when combined with the uniform  $C^2$ -estimates, yields

$$(6.60) \quad |u(t, \cdot)|_{m+2, \alpha, S_0} \leq \text{const}$$

uniformly in  $0 \leq t < \infty$ .

Looking at the equation (4.21) we then deduce

$$(6.61) \quad |\dot{u}(t, \cdot)|_{m, \alpha, S_0} \leq \text{const}$$

uniformly in  $t$ .

(iii) To obtain the estimates for  $D_t^r u$  up to the order

$$(6.62) \quad \left[ \frac{m+2+\alpha}{2} \right]$$

we differentiate the scalar curvature equation with respect to  $t$  as often as necessary and also with respect to the mixed derivatives  $D_t^r D_x^s$  to estimate

$$(6.63) \quad \sum_{1 \leq 2r+s < m+2+\alpha} D_t^r D_x^s u$$

using (6.60), (6.61) and the results from the prior differentiations.

Combined with the estimates for the heat equation in  $\mathbb{R} \times \mathbb{R}^n$  these estimates will also yield the necessary a priori estimates for the Hölder semi-norms in  $\bar{Q}$ , where again the smallness of (6.49) has to be used repeatedly.  $\square$

**6.6. Remark.** The preceding regularity result is also valid in Riemannian manifolds, if the flow hypersurfaces can be written as graphs in a Gaussian coordinate system. In fact the proof is unaware of the nature of the ambient space.

With the method described above the following existence results have been proved in globally hyperbolic spacetimes with a compact Cauchy hypersurface.  $\Omega \subset N$  is always a precompact domain the boundary of which is decomposed as in (6.4) and (6.5) into an upper and lower barrier for the pair  $(F, f)$ . We also apply the stability results from Section 5 and the just proved regularity of the convergence and formulate the theorems accordingly.

By convergence of the flow in  $C^{m+2}$  we mean convergence of the leaves  $M(t) = \text{graph } u(t, \cdot)$  in this norm.

**6.7. Theorem.** *Let  $M_1, M_2$  be lower resp. upper barriers for the pair  $(H, f)$ , where  $f \in C^{m, \alpha}(\bar{\Omega})$  and the  $M_i$  are of class  $C^{m+2, \alpha}$ ,  $4 \leq m$ ,  $0 < \alpha < 1$ , then the curvature flow*

$$(6.64) \quad \begin{aligned} \dot{x} &= (H - f)\nu \\ x(0) &= x_0, \end{aligned}$$

*where  $x_0$  is an embedding of the initial hypersurface  $M_0 = M_2$  exists for all time and converges in  $C^{m+2}$  to a stable solution  $M$  of class  $C^{m+2, \alpha}$  of the equation*

$$(6.65) \quad H|_M = f,$$

*provided the initial hypersurface is not already a solution.*

The existence result was proved in [11, Theorem 2.2], see also [18, Theorem 4.2.1] and the remarks following the theorem. Notice that  $f$  isn't supposed to satisfy any sign condition.

For spacetimes that satisfy the timelike convergence condition and for functions  $f$  with special structural conditions existence results via a mean curvature flow were first proved in [6].

The Gaussian curvature or the curvature functions  $F$  belonging to the larger class  $(K^*)$ , see [10] for a definition, require that the admissible hypersurfaces are strictly convex.

Moreover, proving a priori estimates for the second fundamental form of a hypersurface  $M$  in general semi-Riemannian manifolds, when the curvature function is not the mean curvature, or does not behave similar to it, requires that a strictly convex function  $\chi$  is defined in a neighbourhood of the hypersurface, see Lemma 2.2 on page 3 where sufficient assumptions are stated which imply the existence of strictly convex functions.

Furthermore, when we consider curvature functions of class  $(K^*)$ , notice that the Gaussian curvature belongs to that class, then the right-hand side  $f$  can be defined in  $T(\bar{\Omega})$  instead of  $\bar{\Omega}$ , i.e., in a local trivialization of the tangent bundle  $f$  can be expressed as

$$(6.66) \quad f = f(x, \nu) \quad \wedge \quad \nu \in T_x(N).$$

We shall formulate the existence results with this more general assumption, though of course any stability claim only makes sense for  $f = f(x)$ .

**6.8. Theorem.** *Let  $F \in C^{m,\alpha}(\Gamma_+)$ ,  $4 \leq m$ ,  $0 < \alpha < 1$ , be a curvature function of class  $(K^*)$ , let  $0 < f \in C^{m,\alpha}(T(\bar{\Omega}))$ , and let  $M_1, M_2$  be lower resp. upper barriers for  $(F, f)$  of class  $C^{m+2,\alpha}$ . Then the curvature flow*

$$(6.67) \quad \begin{aligned} \dot{x} &= (\Phi - \tilde{f})\nu \\ x(0) &= x_0 \end{aligned}$$

*where  $\Phi(r) = \log r$  and  $x_0$  is an embedding of  $M_0 = M_2$ , exists for all time and converges in  $C^{m+2}$  to a stationary solution  $M \in C^{m+2,\alpha}$  of the equation*

$$(6.68) \quad F|_M = f$$

*provided the initial hypersurface  $M_2$  is not already a stationary solution and there exists a strictly convex function  $\chi \in C^2(\bar{\Omega})$ .*

*When  $f = f(x)$  and  $F$  is of class  $(D)$ , then  $M$  is stable.*

The theorem was proved in [10] when  $f$  is only defined in  $\bar{\Omega}$  and in the general case in [18, Theorem 4.1.1].

When  $F = H_2$  is the scalar curvature operator, then the requirement that  $f$  is defined in the tangent bundle and not merely in  $N$  is a necessity, if the scalar curvature is to be prescribed. To prove existence results in this case,  $f$

has to satisfy some natural structural conditions, namely,

$$(6.69) \quad 0 < c_1 \leq f(x, \nu) \quad \text{if} \quad \langle \nu, \nu \rangle = -1,$$

$$(6.70) \quad |||f_\beta(x, \nu)||| \leq c_2(1 + |||\nu|||^2),$$

and

$$(6.71) \quad |||f_{\nu^\beta}(x, \nu)||| \leq c_3(1 + |||\nu|||),$$

for all  $x \in \bar{\Omega}$  and all past directed timelike vectors  $\nu \in T_x(\Omega)$ , where  $||| \cdot |||$  is a Riemannian reference metric.

Applying a curvature flow to obtain stationary solutions requires to approximate  $F$  and  $f$  by functions  $F_\epsilon$  and  $f_k$  and to use these functions for the flow. The  $F_\epsilon$  are the  $\epsilon$ -regularizations of  $F$ , which we already discussed before, cf. (5.30) on page 19. Let us also write  $\tilde{F}$  instead of  $F_\epsilon$  as before.

The functions  $f_k$  have the property that  $|||f_{k\beta}|||$  only grows linearly in  $|||\nu|||$  and  $|||f_{k\nu^\beta}(x, \nu)|||$  is bounded. To simplify the presentation we shall therefore assume that  $f$  satisfies

$$(6.72) \quad |||f_\beta(x, \nu)||| \leq c_2(1 + |||\nu|||),$$

$$(6.73) \quad |||f_{\nu^\beta}(x, \nu)||| \leq c_3,$$

and also

$$(6.74) \quad 0 < c_1 \leq f(x, \nu) \quad \forall \nu \in T_x(N), \quad \langle \nu, \nu \rangle < 0,$$

although the last assumption is only a minor point that can easily be dealt with, see [13, Remark 2.6], and [13, Section 7 and 8] for the other approximations of  $f$ .

The barriers  $M_i$ ,  $i = 1, 2$ , for  $(F, f)$  satisfy the barrier condition of course only weakly, i.e., no strict inequalities; however, because of the  $\epsilon$ -regularization we need strict inequalities, so that the  $M_i$ 's are also barriers for  $(\tilde{F}, f)$ , if  $\epsilon$  is small. In [13, Remark 2.4 and Lemma 2.5] it is shown that strict inequalities for the barriers may be assumed without loss of generality.

Now, we can formulate the existence result for the scalar curvature operator  $F = H_2$  under these provisions.

**6.9. Theorem.** *Let  $f \in C^{m, \alpha}(T(\bar{\Omega}))$ ,  $4 \leq m$ ,  $0 < \alpha < 1$ , satisfy the conditions (6.72), (6.73) and (6.74), and let  $M_1, M_2$  be strict lower resp. upper barriers of class  $C^{m+2, \alpha}$  for  $(F, f)$ . Let  $\tilde{F}$  be the  $\epsilon$ -regularization of the scalar curvature operator  $F$ , then the curvature flow for  $\tilde{F}$*

$$(6.75) \quad \begin{aligned} \dot{x} &= (\Phi - \tilde{f}) \\ x(0) &= x_0 \end{aligned}$$

where  $\Phi(r) = r^{\frac{1}{2}}$  and  $x_0$  is an embedding of  $M_0 = M_2$ , exists for all time and converges in  $C^{m+2}$  to a stationary solution  $M_\epsilon \in C^{m+2, \alpha}$  of

$$(6.76) \quad \tilde{F}|_{M_\epsilon} = f$$

provided there exists a strictly convex function  $\chi \in C^2(\bar{\Omega})$  and  $0 < \epsilon$  is small.

The  $M_\epsilon$  then converge in  $C^{m+2}$  to a solution  $M \in C^{m+2,\alpha}$  of

$$(6.77) \quad F|_M = f.$$

If  $f = f(x)$  and  $N$  Einstein, then  $M$  is stable.

These statements, except for the stability and the convergence in  $C^{m+2}$ , are proved in [13].

**6.10. Remark.** Let us now discuss the pure mean curvature flow

$$(6.78) \quad \dot{x} = H\nu$$

with initial spacelike hypersurface  $M_0$  of class  $C^{m+2,\alpha}$ ,  $m \geq 4$  and  $0 < \alpha < 1$ . From the corresponding scalar curvature flow (4.21) on page 12 we immediately infer that the flow moves into the past of  $M_0$ , if

$$(6.79) \quad H|_{M_0} \geq 0$$

and into its future, if

$$(6.80) \quad H|_{M_0} \leq 0.$$

Let us only consider the case (6.79) and also assume that  $M_0$  is not maximal. From the a priori estimates in [11, Section 3 and Section 4] we then deduce that the flow remains smooth as long as it stays in a compact set of  $N$ , and if a compact, spacelike hypersurface  $M_1$  of class  $C^2$  satisfying

$$(6.81) \quad H|_{M_1} \leq 0$$

lies in the past of  $M_0$ , then the flow will exist for all time and converge in  $C^{m+2}$  to a stable maximal hypersurface  $M$ , hence a neighbourhood of  $M$  can be foliated by CMC hypersurfaces, where those in the future of  $M$  have positive mean curvature, in view of Remark 5.7 on page 24.

Thus, the flow will converge if and only if such a hypersurface  $M_1$  lies in the past of  $M_0$ .

Conversely, if there exists a compact, spacelike hypersurface  $M_1$  in  $N$  satisfying (6.81), and there is no stable maximal hypersurface in its future, then this is a strong indication that  $N$  has no future singularity, assuming that such a singularity would produce spacelike hypersurfaces with positive mean curvature.

An example of such a spacetime is the  $(n+1)$ -dimensional de Sitter space which is geodesically complete and has exactly one maximal hypersurface  $M$  which is also totally geodesic but not stable, and the future resp. past of  $M$  are foliated by coordinate slices with negative resp. positive mean curvature.

To conclude this section let us show which spacelike hypersurfaces satisfy  $C^1$ -estimates automatically.

**6.11. Theorem.** *Let  $M = \text{graph } u|_{\mathcal{S}_0}$  be a compact, spacelike hypersurface represented in a Gaussian coordinate system with unilateral bounded principal curvatures, e.g.,*

$$(6.82) \quad \kappa_i \geq \kappa_0 \quad \forall i.$$

*Then, the quantity  $\tilde{v} = \frac{1}{\sqrt{1-|Du|^2}}$  can be estimated by*

$$(6.83) \quad \tilde{v} \leq c(|u|, \mathcal{S}_0, \sigma_{ij}, \psi, \kappa_0),$$

*where we assumed that in the Gaussian coordinate system the ambient metric has the form as in (6.1).*

*Proof.* We suppose as usual that the Gaussian coordinate system is future oriented, and that the second fundamental form is evaluated with respect to the past directed normal. We observe that

$$(6.84) \quad \|Du\|^2 = g^{ij}u_iu_j = e^{-2\psi} \frac{|Du|^2}{v^2},$$

hence, it is equivalent to find an a priori estimate for  $\|Du\|$ .

Let  $\lambda$  be a real parameter to be specified later, and set

$$(6.85) \quad w = \frac{1}{2} \log \|Du\|^2 + \lambda u.$$

We may regard  $w$  as being defined on  $\mathcal{S}_0$ ; thus, there is  $x_0 \in \mathcal{S}_0$  such that

$$(6.86) \quad w(x_0) = \sup_{\mathcal{S}_0} w,$$

and we conclude

$$(6.87) \quad 0 = w_i = \frac{1}{\|Du\|^2} u_{ij}u^j + \lambda u_i$$

in  $x_0$ , where the covariant derivatives are taken with respect to the induced metric  $g_{ij}$ , and the indices are also raised with respect to that metric.

Expressing the second fundamental form of a graph with the help of the Hessian of the function

$$(6.88) \quad e^{-\psi}v^{-1}h_{ij} = -u_{ij} - \bar{F}_{00}^0 u_i u_j - \bar{F}_{0i}^0 u_j - \bar{F}_{0j}^0 u_i - \bar{F}_{ij}^0.$$

we deduce further

$$(6.89) \quad \begin{aligned} \lambda \|Du\|^4 &= -u_{ij}u^i u^j \\ &= e^{-\psi} \tilde{v} h_{ij} u^i u^j + \bar{F}_{00}^0 \|Du\|^4 \\ &\quad + 2\bar{F}_{0j}^0 u^j \|Du\|^2 + \bar{F}_{ij}^0 u^i u^j. \end{aligned}$$

Now, there holds

$$(6.90) \quad u^i = g^{ij}u_j = e^{-2\psi} \sigma^{ij} u_j v^{-2},$$

and by assumption,

$$(6.91) \quad h_{ij}u^i u^j \geq \kappa_0 \|Du\|^2,$$

i.e., the critical terms on the right-hand side of (6.89) are of fourth order in  $\|Du\|$  with bounded coefficients, and we conclude that  $\|Du\|$  can't be too large in  $x_0$  if we choose  $\lambda$  such that

$$(6.92) \quad \lambda \leq -c\|\bar{F}_{\alpha\beta}^0\| - 1$$

with a suitable constant  $c$ ;  $w$ , or equivalently,  $\|Du\|$  is therefore uniformly bounded from above.  $\square$

Especially for convex graphs over  $\mathcal{S}_0$  the term  $\tilde{v}$  is uniformly bounded as long as they stay in a compact set.

## 7. THE INVERSE MEAN CURVATURE FLOW

Let us now consider the inverse mean curvature flow (IMCF)

$$(7.1) \quad \dot{x} = -H^{-1}\nu$$

with initial hypersurface  $M_0$  in a globally hyperbolic spacetime  $N$  with compact Cauchy hypersurface  $\mathcal{S}_0$ .

$N$  is supposed to satisfy the timelike convergence condition

$$(7.2) \quad \bar{R}_{\alpha\beta}\nu^\alpha\nu^\beta \geq 0 \quad \forall \langle \nu, \nu \rangle = -1.$$

Spacetimes with compact Cauchy hypersurface that satisfy the timelike convergence condition are also called *cosmological spacetimes*, a terminology due to Bartnik.

In such spacetimes the inverse mean curvature flow will be smooth as long as it stays in a compact set, and, if  $H|_{M_0} > 0$  and if the flow exists for all time, it will necessarily run into the future singularity, since the mean curvature of the flow hypersurfaces will become unbounded and the flow will run into the future of  $M_0$ . Hence the claim follows from Remark 6.4 on page 28.

However, it might be that the flow will run into the singularity in finite time. To exclude this behaviour we introduced in [15] the so-called *strong volume decay condition*, cf. Definition 7.2. A strong volume decay condition is both necessary and sufficient in order that the IMCF exists for all time.

**7.1. Theorem.** *Let  $N$  be a cosmological spacetime with compact Cauchy hypersurface  $\mathcal{S}_0$  and with a future mean curvature barrier. Let  $M_0$  be a closed, connected, spacelike hypersurface with positive mean curvature and assume furthermore that  $N$  satisfies a future volume decay condition. Then the IMCF (7.1) with initial hypersurface  $M_0$  exists for all time and provides a foliation of the future  $D^+(M_0)$  of  $M_0$ .*

*The evolution parameter  $t$  can be chosen as a new time function. The flow hypersurfaces  $M(t)$  are the slices  $\{t = \text{const}\}$  and their volume satisfies*

$$(7.3) \quad |M(t)| = |M_0|e^{-t}.$$

*Defining a new time function  $\tau$  by choosing*

$$(7.4) \quad \tau = 1 - e^{-\frac{1}{n}t}$$

we obtain  $0 \leq \tau < 1$ ,

$$(7.5) \quad |M(\tau)| = |M_0|(1 - \tau)^n,$$

and the future singularity corresponds to  $\tau = 1$ .

Moreover, the length  $L(\gamma)$  of any future directed curve  $\gamma$  starting from  $M(\tau)$  is bounded from above by

$$(7.6) \quad L(\gamma) \leq c(1 - \tau),$$

where  $c = c(n, M_0)$ . Thus, the expression  $1 - \tau$  can be looked at as the radius of the slices  $\{\tau = \text{const}\}$  as well as a measure of the remaining life span of the spacetime.

Next we shall define the strong volume decay condition.

**7.2. Definition.** Suppose there exists a time function  $x^0$  such that the future end of  $N$  is determined by  $\{\tau_0 \leq x^0 < b\}$  and the coordinate slices  $M_\tau = \{x^0 = \tau\}$  have positive mean curvature with respect to the past directed normal for  $\tau_0 \leq \tau < b$ . In addition the volume  $|M_\tau|$  should satisfy

$$(7.7) \quad \lim_{\tau \rightarrow b} |M_\tau| = 0.$$

A decay like that is normally associated with a future singularity and we simply call it *volume decay*. If  $(g_{ij})$  is the induced metric of  $M_\tau$  and  $g = \det(g_{ij})$ , then we have

$$(7.8) \quad \log g(\tau_0, x) - \log g(\tau, x) = \int_{\tau_0}^{\tau} 2e^\psi \bar{H}(s, x) \quad \forall x \in \mathcal{S}_0,$$

where  $\bar{H}(\tau, x)$  is the mean curvature of  $M_\tau$  in  $(\tau, x)$ . This relation can be easily derived from the relation (3.8) on page 5 and Remark 3.6 on page 7. A detailed proof is given in [12].

In view of (7.7) the left-hand side of this equation tends to infinity if  $\tau$  approaches  $b$  for a.e.  $x \in \mathcal{S}_0$ , i.e.,

$$(7.9) \quad \lim_{\tau \rightarrow b} \int_{\tau_0}^{\tau} e^\psi \bar{H}(s, x) = \infty \quad \text{for a.e. } x \in \mathcal{S}_0.$$

Assume now, there exists a continuous, positive function  $\varphi = \varphi(\tau)$  such that

$$(7.10) \quad e^\psi \bar{H}(\tau, x) \geq \varphi(\tau) \quad \forall (\tau, x) \in (\tau_0, b) \times \mathcal{S}_0,$$

where

$$(7.11) \quad \int_{\tau_0}^b \varphi(\tau) = \infty,$$

then we say that the future of  $N$  satisfies a *strong volume decay condition*.

**7.3. Remark.** (i) By approximation we may assume that the function  $\varphi$  above is smooth.

(ii) A similar definition holds for the past of  $N$  by simply reversing the time direction. Notice that in this case the mean curvature of the coordinate slices has to be negative.

**7.4. Lemma.** *Suppose that the future of  $N$  satisfies a strong volume decay condition, then there exist a time function  $\tilde{x}^0 = \tilde{x}^0(x^0)$ , where  $x^0$  is the time function in the strong volume decay condition, such that the mean curvature  $\tilde{H}$  of the slices  $\tilde{x}^0 = \text{const}$  satisfies the estimate*

$$(7.12) \quad e^{\tilde{\psi}} \tilde{H} \geq 1.$$

The factor  $e^{\tilde{\psi}}$  is now the conformal factor in the representation

$$(7.13) \quad d\tilde{s}^2 = e^{2\tilde{\psi}} (-(d\tilde{x}^0)^2 + \sigma_{ij} d\tilde{x}^i d\tilde{x}^j).$$

The range of  $\tilde{x}^0$  is equal to the interval  $[0, \infty)$ , i.e., the singularity corresponds to  $\tilde{x}^0 = \infty$ .

A proof is given in [15, Lemma 1.4].

**7.5. Remark.** Theorem 7.1 can be generalized to spacetimes satisfying

$$(7.14) \quad \bar{R}_{\alpha\beta} \nu^\alpha \nu^\beta \geq -\Lambda \quad \forall \langle \nu, \nu \rangle = -1$$

with a constant  $\Lambda \geq 0$ , if the mean curvature of the initial hypersurface  $M_0$  is sufficiently large

$$(7.15) \quad H|_{M_0} > \sqrt{n\Lambda},$$

cf. [25]. In that thesis it is also shown that the future mean curvature barrier assumption can be dropped, i.e., the strong volume decay condition is sufficient to prove that the IMCF exists for all time and provides a foliation of the future of  $M_0$ . Hence, the strong volume decay condition already implies the existence of a future mean curvature barrier, since the leaves of the IMCF define such a barrier.

## 8. THE IMCF IN ARW SPACES

In the present section we consider spacetimes  $N$  satisfying some structural conditions, which are still fairly general, and prove convergence results for the leaves of the IMCF.

Moreover, we define a new spacetime  $\hat{N}$  by switching the light cone and using reflection to define a new time function, such that the two spacetimes  $N$  and  $\hat{N}$  can be pasted together to yield a smooth manifold having a metric singularity, which, when viewed from the region  $N$  is a big crunch, and when viewed from  $\hat{N}$  is a big bang.

The inverse mean curvature flows in  $N$  resp.  $\hat{N}$  correspond to each other via reflection. Furthermore, the properly rescaled flow in  $N$  has a natural smooth extension of class  $C^3$  across the singularity into  $\hat{N}$ . With respect to this natural diffeomorphism we speak of a transition from big crunch to big bang.

**8.1. Definition.** A globally hyperbolic spacetime  $N$ ,  $\dim N = n + 1$ , is said to be *asymptotically Robertson-Walker* (ARW) with respect to the future, if a future end of  $N$ ,  $N_+$ , can be written as a product  $N_+ = [a, b) \times \mathcal{S}_0$ , where  $\mathcal{S}_0$  is a Riemannian space, and there exists a future directed time function  $\tau = x^0$  such that the metric in  $N_+$  can be written as

$$(8.1) \quad d\tilde{s}^2 = e^{2\tilde{\psi}} \{-(dx^0)^2 + \sigma_{ij}(x^0, x) dx^i dx^j\},$$

where  $\mathcal{S}_0$  corresponds to  $x^0 = a$ ,  $\tilde{\psi}$  is of the form

$$(8.2) \quad \tilde{\psi}(x^0, x) = f(x^0) + \psi(x^0, x),$$

and we assume that there exists a positive constant  $c_0$  and a smooth Riemannian metric  $\bar{\sigma}_{ij}$  on  $\mathcal{S}_0$  such that

$$(8.3) \quad \lim_{\tau \rightarrow b} e^{\psi} = c_0 \quad \wedge \quad \lim_{\tau \rightarrow b} \sigma_{ij}(\tau, x) = \bar{\sigma}_{ij}(x),$$

and

$$(8.4) \quad \lim_{\tau \rightarrow b} f(\tau) = -\infty.$$

Without loss of generality we shall assume  $c_0 = 1$ . Then  $N$  is ARW with respect to the future, if the metric is close to the Robertson-Walker metric

$$(8.5) \quad d\bar{s}^2 = e^{2f} \{-dx^{0^2} + \bar{\sigma}_{ij}(x) dx^i dx^j\}$$

near the singularity  $\tau = b$ . By *close* we mean that the derivatives of arbitrary order with respect to space and time of the conformal metric  $e^{-2f} \check{g}_{\alpha\beta}$  in (8.1) should converge to the corresponding derivatives of the conformal limit metric in (8.5) when  $x^0$  tends to  $b$ . We emphasize that in our terminology Robertson-Walker metric does not imply that  $(\bar{\sigma}_{ij})$  is a metric of constant curvature, it is only the spatial metric of a warped product.

We assume, furthermore, that  $f$  satisfies the following five conditions

$$(8.6) \quad -f' > 0,$$

there exists  $\omega \in \mathbb{R}$  such that

$$(8.7) \quad n + \omega - 2 > 0 \quad \wedge \quad \lim_{\tau \rightarrow b} |f'|^2 e^{(n+\omega-2)f} = m > 0.$$

Set  $\tilde{\gamma} = \frac{1}{2}(n + \omega - 2)$ , then there exists the limit

$$(8.8) \quad \lim_{\tau \rightarrow b} (f'' + \tilde{\gamma}|f'|^2)$$

and

$$(8.9) \quad |D_\tau^m (f'' + \tilde{\gamma}|f'|^2)| \leq c_m |f'|^m \quad \forall m \geq 1,$$

as well as

$$(8.10) \quad |D_\tau^m f| \leq c_m |f'|^m \quad \forall m \geq 1.$$

If  $\mathcal{S}_0$  is compact, then we call  $N$  a *normalized* ARW spacetime, if

$$(8.11) \quad \int_{\mathcal{S}_0} \sqrt{\det \bar{\sigma}_{ij}} = |S^n|.$$

**8.2. Remark.** (i) If these assumptions are satisfied, then the range of  $\tau$  is finite, hence, we may—and shall—assume w.l.o.g. that  $b = 0$ , i.e.,

$$(8.12) \quad a < \tau < 0.$$

(ii) Any ARW spacetime with compact  $\mathcal{S}_0$  can be normalized as one easily checks. For normalized ARW spaces the constant  $m$  in (8.7) is defined uniquely and can be identified with the mass of  $N$ , cf. [20].

(iii) In view of the assumptions on  $f$  the mean curvature of the coordinate slices  $M_\tau = \{x^0 = \tau\}$  tends to  $\infty$ , if  $\tau$  goes to zero.

(iv) ARW spaces with compact  $\mathcal{S}_0$  satisfy a strong volume decay condition, cf. Definition 7.2 on page 40.

(v) Similarly one can define  $N$  to be ARW with respect to the past. In this case the singularity would lie in the past, correspond to  $\tau = 0$ , and the mean curvature of the coordinate slices would tend to  $-\infty$ .

We assume that  $N$  satisfies the timelike convergence condition and that  $\mathcal{S}_0$  is compact. Consider the future end  $N_+$  of  $N$  and let  $M_0 \subset N_+$  be a spacelike hypersurface with positive mean curvature  $\check{H}|_{M_0} > 0$  with respect to the past directed normal vector  $\check{\nu}$ —it will become apparent in a moment why we use the symbols  $\check{H}$  and  $\check{\nu}$  and not the usual ones  $H$  and  $\nu$ . Then, as we have proved in the preceding section, the inverse mean curvature flow

$$(8.13) \quad \dot{x} = -\check{H}^{-1}\check{\nu}$$

with initial hypersurface  $M_0$  exists for all time, is smooth, and runs straight into the future singularity.

If we express the flow hypersurfaces  $M(t)$  as graphs over  $\mathcal{S}_0$

$$(8.14) \quad M(t) = \text{graph } u(t, \cdot),$$

then we have proved in [14]

**8.3. Theorem.** (i) *Let  $N$  satisfy the above assumptions, then the range of the time function  $x^0$  is finite, i.e., we may assume that  $b = 0$ . Set*

$$(8.15) \quad \tilde{u} = ue^{\gamma t},$$

*where  $\gamma = \frac{1}{n}\tilde{\gamma}$ , then there are positive constants  $c_1, c_2$  such that*

$$(8.16) \quad -c_2 \leq \tilde{u} \leq -c_1 < 0,$$

*and  $\tilde{u}$  converges in  $C^\infty(\mathcal{S}_0)$  to a smooth function, if  $t$  goes to infinity. We shall also denote the limit function by  $\tilde{u}$ .*

(ii) *Let  $\check{g}_{ij}$  be the induced metric of the leaves  $M(t)$ , then the rescaled metric*

$$(8.17) \quad e^{\frac{2}{n}t}\check{g}_{ij}$$

*converges in  $C^\infty(\mathcal{S}_0)$  to*

$$(8.18) \quad (\tilde{\gamma}m)^{\frac{1}{\tilde{\gamma}}}(-\tilde{u})^{\frac{2}{\tilde{\gamma}}}\bar{\sigma}_{ij}.$$

(iii) *The leaves  $M(t)$  get more umbilical, if  $t$  tends to infinity, namely, there holds*

$$(8.19) \quad \check{H}^{-1} |\check{h}_i^j - \frac{1}{n} \check{H} \delta_i^j| \leq c e^{-2\gamma t}.$$

*In case  $n + \omega - 4 > 0$ , we even get a better estimate*

$$(8.20) \quad |\check{h}_i^j - \frac{1}{n} \check{H} \delta_i^j| \leq c e^{-\frac{1}{2n}(n+\omega-4)t}.$$

To prove the convergence results for the inverse mean curvature flow, we consider the flow hypersurfaces to be embedded in  $N$  equipped with the conformal metric

$$(8.21) \quad d\bar{s}^2 = -(dx^0)^2 + \sigma_{ij}(x^0, x) dx^i dx^j.$$

Though, formally, we have a different ambient space we still denote it by the same symbol  $N$  and distinguish only the metrics  $\check{g}_{\alpha\beta}$  and  $\bar{g}_{\alpha\beta}$

$$(8.22) \quad \check{g}_{\alpha\beta} = e^{2\check{\psi}} \bar{g}_{\alpha\beta}$$

and the corresponding geometric quantities of the hypersurfaces  $\check{h}_{ij}, \check{g}_{ij}, \check{\nu}$  resp.  $h_{ij}, g_{ij}, \nu$ , etc., i.e., the standard notations now apply to the case when  $N$  is equipped with the metric in (8.21).

The second fundamental forms  $\check{h}_i^j$  and  $h_i^j$  are related by

$$(8.23) \quad e^{\check{\psi}} \check{h}_i^j = h_i^j + \check{\psi}_\alpha \nu^\alpha \delta_i^j$$

and, if we define  $F$  by

$$(8.24) \quad F = e^{\check{\psi}} \check{H},$$

then

$$(8.25) \quad F = H - n\tilde{v}f' + n\psi_\alpha \nu^\alpha,$$

where

$$(8.26) \quad \tilde{v} = v^{-1},$$

and the evolution equation can be written as

$$(8.27) \quad \dot{x} = -F^{-1}\nu,$$

since

$$(8.28) \quad \check{\nu} = e^{-\check{\psi}} \nu.$$

The flow exists for all time and is smooth, due to the results in the preceding section.

Next, we want to show how the metric, the second fundamental form, and the normal vector of the hypersurfaces  $M(t)$  evolve by adapting the general evolution equations in Section 3 on page 4 to the present situation.

**8.4. Lemma.** *The metric, the normal vector, and the second fundamental form of  $M(t)$  satisfy the evolution equations*

$$(8.29) \quad \dot{g}_{ij} = -2F^{-1}h_{ij},$$

$$(8.30) \quad \dot{\nu} = \nabla_M(-F^{-1}) = g^{ij}(-F^{-1})_i x_j,$$

and

$$(8.31) \quad \dot{h}_i^j = (-F^{-1})_i^j + F^{-1}h_i^k h_k^j + F^{-1}\bar{R}_{\alpha\beta\gamma\delta}\nu^\alpha x_i^\beta \nu^\gamma x_k^\delta g^{kj}$$

$$(8.32) \quad \dot{h}_{ij} = (-F^{-1})_{ij} - F^{-1}h_i^k h_{kj} + F^{-1}\bar{R}_{\alpha\beta\gamma\delta}\nu^\alpha x_i^\beta \nu^\gamma x_j^\delta.$$

Since the initial hypersurface is a graph over  $\mathcal{S}_0$ , we can write

$$(8.33) \quad M(t) = \text{graph } u(t)|_{\mathcal{S}_0} \quad \forall t \in I,$$

where  $u$  is defined in the cylinder  $\mathbb{R}_+ \times \mathcal{S}_0$ . We then deduce from (8.27), looking at the component  $\alpha = 0$ , that  $u$  satisfies a parabolic equation of the form

$$(8.34) \quad \dot{u} = \frac{\tilde{v}}{F},$$

where we emphasize that the time derivative is a total derivative, i.e.

$$(8.35) \quad \dot{u} = \frac{\partial u}{\partial t} + u_i \dot{x}^i.$$

Since the past directed normal can be expressed as

$$(8.36) \quad (\nu^\alpha) = -e^{-\psi} v^{-1} (1, u^i),$$

we conclude from (8.34)

$$(8.37) \quad \frac{\partial u}{\partial t} = \frac{v}{F}.$$

For this new curvature flow the necessary decay estimates and convergence results can be proved, which in turn can be immediately translated to corresponding convergence results for the original IMCF.

*Transition from big crunch to big bang*

With the help of the convergence results in Theorem 8.3, we can rescale the IMCF such that it can be extended past the singularity in a natural way.

We define a new spacetime  $\hat{N}$  by reflection and time reversal such that the IMCF in the old spacetime transforms to an IMCF in the new one.

By switching the light cone we obtain a new spacetime  $\hat{N}$ . The flow equation in  $N$  is independent of the time orientation, and we can write it as

$$(8.38) \quad \dot{x} = -\check{H}^{-1}\check{\nu} = -(-\check{H})^{-1}(-\check{\nu}) \equiv -\hat{H}^{-1}\hat{\nu},$$

where the normal vector  $\hat{\nu} = -\check{\nu}$  is past directed in  $\hat{N}$  and the mean curvature  $\hat{H} = -\check{H}$  negative.

Introducing a new time function  $\hat{x}^0 = -x^0$  and formally new coordinates  $(\hat{x}^\alpha)$  by setting

$$(8.39) \quad \hat{x}^0 = -x^0, \quad \hat{x}^i = x^i,$$

we define a spacetime  $\hat{N}$  having the same metric as  $N$ —only expressed in the new coordinate system—such that the flow equation has the form

$$(8.40) \quad \dot{\hat{x}} = -\hat{H}^{-1}\hat{\nu},$$

where  $M(t) = \text{graph } \hat{u}(t)$ ,  $\hat{u} = -u$ , and

$$(8.41) \quad (\hat{\nu}^\alpha) = -\tilde{\nu}e^{-\tilde{\psi}}(1, \hat{u}^i)$$

in the new coordinates, since

$$(8.42) \quad \hat{\nu}^0 = -\tilde{\nu}^0 \frac{\partial \hat{x}^0}{\partial x^0} = \nu^0$$

and

$$(8.43) \quad \hat{\nu}^i = -\tilde{\nu}^i.$$

The singularity in  $\hat{x}^0 = 0$  is now a past singularity, and can be referred to as a big bang singularity.

The union  $N \cup \hat{N}$  is a smooth manifold, topologically a product  $(-a, a) \times \mathcal{S}_0$ —we are well aware that formally the singularity  $\{0\} \times \mathcal{S}_0$  is not part of the union; equipped with the respective metrics and time orientation it is a spacetime which has a (metric) singularity in  $x^0 = 0$ . The time function

$$(8.44) \quad \hat{x}^0 = \begin{cases} x^0, & \text{in } N, \\ -x^0, & \text{in } \hat{N}, \end{cases}$$

is smooth across the singularity and future directed.

$N \cup \hat{N}$  can be regarded as a *cyclic universe* with a contracting part  $N = \{\hat{x}^0 < 0\}$  and an expanding part  $\hat{N} = \{\hat{x}^0 > 0\}$  which are joined at the singularity  $\{\hat{x}^0 = 0\}$ .

It turns out that the inverse mean curvature flow, properly rescaled, defines a natural  $C^3$ -diffeomorphism across the singularity and with respect to this diffeomorphism we speak of a transition from big crunch to big bang.

Using the time function in (8.44) the inverse mean curvature flows in  $N$  and  $\hat{N}$  can be uniformly expressed in the form

$$(8.45) \quad \dot{\hat{x}} = -\hat{H}^{-1}\hat{\nu},$$

where (8.45) represents the original flow in  $N$ , if  $\hat{x}^0 < 0$ , and the flow in (8.40), if  $\hat{x}^0 > 0$ .

Let us now introduce a new flow parameter

$$(8.46) \quad s = \begin{cases} -\gamma^{-1}e^{-\gamma t}, & \text{for the flow in } N, \\ \gamma^{-1}e^{-\gamma t}, & \text{for the flow in } \hat{N}, \end{cases}$$

and define the flow  $y = y(s)$  by  $y(s) = \hat{x}(t)$ .  $y = y(s, \xi)$  is then defined in  $[-\gamma^{-1}, \gamma^{-1}] \times \mathcal{S}_0$ , smooth in  $\{s \neq 0\}$ , and satisfies the evolution equation

$$(8.47) \quad y' \equiv \frac{d}{ds}y = \begin{cases} -\hat{H}^{-1}\hat{\nu}e^{\gamma t}, & s < 0, \\ \hat{H}^{-1}\hat{\nu}e^{\gamma t}, & s > 0. \end{cases}$$

In [14] we proved:

**8.5. Theorem.** *The flow  $y = y(s, \xi)$  is of class  $C^3$  in  $(-\gamma^{-1}, \gamma^{-1}) \times \mathcal{S}_0$  and defines a natural diffeomorphism across the singularity. The flow parameter  $s$  can be used as a new time function.*

**8.6. Remark.** The regularity result for the transition flow is optimal, i.e., given any  $0 < \alpha < 1$ , then there is an ARW space such that the transition flow is not of class  $C^{3,\alpha}$ , cf. [19].

**8.7. Remark.** Since ARW spaces have a future mean curvature barrier, a future end can be foliated by CMC hypersurfaces the mean curvature of which can be used as a new time function., see [9] and [22]. In [8] we study this foliation a bit more closely and prove that, when writing the CMC hypersurfaces as graphs  $M_\tau = \text{graph } \varphi(\tau, \cdot)$  in the special coordinate system of the ARW space, where  $\tau$  is the mean curvature, of  $M_\tau$  then

$$(8.48) \quad \tau(-\varphi)^{1+\tilde{\gamma}^{-1}} \rightarrow \text{const} > 0,$$

notice that  $\varphi < 0$ , and hence

$$(8.49) \quad \lim_{\tau \rightarrow \infty} \frac{\varphi(\tau, x)}{\varphi(\tau, y)} = 1 \quad \forall x, y \in \mathcal{S}_0.$$

Moreover, the new time function

$$(8.50) \quad s = -\tau^{-q}, \quad q = \frac{\tilde{\gamma}}{1 + \tilde{\gamma}}$$

can be extended to the mirror universe  $\hat{N}$  by odd reflection as a function of class  $C^3$  across the singularity with non-vanishing gradient.
