Abstract

Context. Spectral variability is the main tool for constraining emission models of BL Lac objects.

Aims. By means of systematic observations of the BL Lac prototype PKS 2155-304 in the infrared-optical band, we explore variability on the scales of months, days and hours.

Methods. We made our observations with the robotic 60 cm telescope REM located at La Silla, Chile. VRIJHK filters were used.

Results. PKS 2155-304 was observed from May to December 2005. The wavelength interval explored, the total number of photometric points and the short integration time render our photometry substantially superior to previous ones for this source. On the basis of the intensity and colour we distinguish three different states of the source, each of duration of months, which include all those described in the literature. In particular, we report the highest state ever detected in the H band. The source varied by a factor of 4 in this band, much more than in the V band (a factor ≈ 2). The source softened with increasing intensity, contrary to the general pattern observed in the UV-X-ray bands. On five nights of November we had nearly continuous monitoring for 2-3 hours. A variability episode with a time scale of $\tau \approx 24$ h is well documented, a much more rapid flare with $\tau=1-2$ h, is also apparent, but is supported by relatively few points.

Conclusions. The overall spectral energy distribution of PKS 2155-304 is commonly described by a synchrotron-self-Compton model. The optical infrared emission is however in excess of the expectation of the model, in its original formulation. This can be explained by a variation of the frequency of the synchrotron peak, which is not unprecedented in BL Lacs.

Key words. galaxies: active - galaxies: BL Lacertae objects: PKS 2155-304

1. Introduction

PKS 2155-304 (z=0.116, Falomo et al. 1991) is a prototype of high frequency peaked BL Lac objects. It has been observed in the entire electromagnetic spectrum, from radio to TeV gamma-rays. It was the target of several multifrequency campaigns, the main scope of which was to study the variability of the spectral energy distribution (SED), in order to constrain emission models.

In particular we refer to the 1991 and 1994 campaigns involving IUE, ROSAT, ASCA, EUVE and ground based telescopes (see Edelson et al. 1995, Urry et al. 1997, and references therein). There were noticeable differences in source behaviour between these two epochs. While in 1991 the multiwavelength variability was almost achromatic, and the X-ray variation led that in the UV by a couple of hours, in 1994 the variability was more pronounced in X-rays than in UV-optical, with a lag of the latter

| September | 8 | 159 | 18080 s |
| October | 3 | 102 | 11590 s |
| November | 21 | 1581 | 173540 s |
| December | 6 | 64 | 7030 s |

Table 1. Outline of observations accomplished in 2005.

by two days. The general pattern was that of a hardening of the spectrum with increasing intensity. More recently Zhang et al. (2006b) studied a large set of data covering the period 2000-2005 obtained with the XMM-Newton satellite, which allowed a direct comparison of the X-ray and UV-optical band, the latter deriving from the Optical Monitor on board the satellite. The complexity of the variability pattern is confirmed. Some episodes of achromatic variation were detected, but a general tendency of increasing variability amplitude with increasing frequency, and spectral hardening with increasing intensity was found.

Optical photometry has been performed by several groups in several occasions (see e.g. Miller et al. (1983), Smith et al. (1992), Xie et al. (1996), Paltani et al. (1997), Pesce et al. (1997), Fan & Lin (2000), Tommasi et al. (2001) and references therein). All this material is rather fragmented, consisting of few hours of observations during few nights. The difficulty of a systematic observing campaign covering many nights is partly overcome by the possibility of observing using remotely guided or robotic telescopes.

The REM telescope, originally designed for a prompt detection of gamma ray bursts (see Molinari et al. (2006)), is particularly apt for photometric studies of BL Lacs (see also the previous results for PKS 0537-441 by Dolcini et al. 2005, and for 3C 454.3 by Fuhrmann et al. 2006) and, being located at La Silla (Chile), it is ideally fit to study PKS 2155-304.

We report on extensive and intensive photometric campaign performed in 2005 in the V, R, I, J, H, K bands. For the total number of photometric points, for the time resolution (minutes) and spectral range this campaign seems to supersede all the IR-optical photometric material presented thus far.

2. REM, Photometric procedure, data analysis

2.1. REM

The Rapid Eye Mount (REM) Telescope is a 60 cm fully robotic instrument. It has two cameras fed at the same time by a dichroic filter that allows the telescope to observe in the NIR (z', J, H, K) as well as optical (I, R, V). Further information on the REM project may be found in Zerbi et al. (2001), Chincarini et al. (2003) and Covino et al. (2004).

2.2. Observations and data analysis

REM observed the PKS 2155-304 field during May, September, October, November and December 2005 in VRIH bands. Only during three nights in September the telescope observed also in J and K filters. To allow intranight and short time-scale variability monitoring, very intensive observations (2-3 h, quasi-continuously) were made during five of the nights in November. An outline of the observations is reported in Table 1, while the complete log is only available in Table A.1 (see Appendix A): we report for each photometric point the band, the epoch, the integration time, the intensity and its uncertainty. Typical integration times are ≤ 100 s and statistical uncertainties are always $\leq 10\%$ and $\leq 3\%$ in the highest state (November 2005, see following).

Reduction of the REM NIR and optical frames followed standard procedures. Photometric analysis of the frames was done using the GAIA¹ and DAOPHOT packages (Stetson 1986). Relative calibration was obtained by calculating magnitude shifts relative to three bright isolated stars in the field, indicated by A, B, C in Fig. 1 (image taken from ESO Digitized Sky Survey²).

The NIR frames were calibrated using the magnitudes of the A, B and C stars as reported in the 2MASS catalogue³. For the optical, we exposed on 2006 June 29 the standard field G156-31 (Landolt, 1992), and immediately after this the PKS 2155-304 field. We calculated the zero points which were then used to calibrate all of our data. The observed magnitudes in the REM filters for the reference objects A, B, and C are reported in Table 2. We have monitored the relative intensities of the A, B, C reference stars during the entire observation period, and we have detected no indication of variability within 0.1 mag (error on the average \leq 0.01 mag).

Table 2. Coordinates, IR and optical magnitudes for the reference stars.

Note that we found significant deviations from the optical calibrations provided by the finding charts for AGN of the Heidelberg University⁴ (Hamuy & Maza, 1989). In particular the star C is also used as a calibrator by these authors and our optical zeropoint differs by about 0.3 mag from theirs.

Relative and absolute calibration errors have been added in quadrature to the photometric error derived from the procedure.

3. Results

3.1. Long term variability

In this section we report the results of the long term photometric analysis. The light curves in the H, R, I, V filters are given in Fig. 2.

The intensity is normalized with respect to the average over the entire observation period. These averages are given in Table 3. It is immediately apparent that the total variability range is very different in the various filters, being a factor ≈ 4 in H and a factor ≈ 2 in V (see Table 3) . The shapes of the light curves are similar in the various filters. A flare-like structure is apparent in all filters at t ≈ 680 (first days of November). The ratio between the V- and H-band fluxes, designated as V/H, is reported in Fig. 3. In order not to introduce spurious effects due to small time scale variability, the V/H ratio has been computed for pairs of V and H measurements spaced apart in time by no more than 10 minutes.

It seems that there are two main colour states: the source softens rather abruptly, in response to the November flare. On the basis of the light curve and the colour curve we divide the observations in three epochs: **1** 500-525, **2** 640-660, **3** 670-725, expressed in MJD⁵.

Table 3. Average intensities for all epochs and all filters. All data are in mJy units. **Epoch 1** corresponds to May 2005 observations, **epoch 2** to September-October 2005 observations and **epoch 3** to November-December 2005 observations.

3.2. Short time-scale variability

We report in Fig. 4 the light curves for five nights in November 2005, when the observations were more intensive. All the nights belong to epoch 3, corresponding to the high state of the source.

The mean intensity and the 1-sigma values for each night are given in Table 4.

A χ^2 analysis indicates that in each night the significance of variability is very high, but for the nights of Nov 4 and Nov 18 for the H band and Nov 19 for the V band. In the box of Nov 4 - V band we also report the photometry of a comparison star which illustrates directly the significance of the source variability. Though the shapes of intensity curves are different (see Fig. 4), there is a rather regular colour-intensity dependence (see Fig. 5) indicating harder states for higher intensities.

4), there is a rather regular colour-intensity dependence (see Fig. 5) indicating harder states for higher intensities. We adopt the usual definition of time scale variability $\tau = \frac{1}{1+z} \frac{\langle f \rangle}{df/dt}$. Following Montagni et al. (2006), a variability time scale is taken as reliable if the light curve can be approximated with a linear dependence, and it contains at least 10 points. In particular this gives a time scale of ≈ 24 h for the November 4 night (Fig. 4, V band - Nov 4 box). The simultaneous H light curve does not show any regular variability. We note that on November 8 in the H curve there is a flare-like event. If one connects 4 points

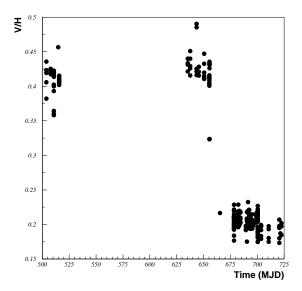

Figure 3. V/H flux ratio evolution during 2005. Error bars are comparable with symbol size.

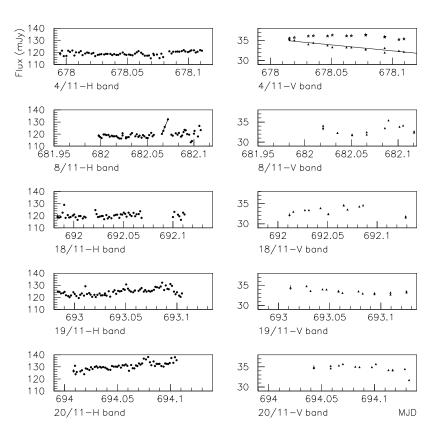

Figure 4. Light curves in the H and V filters for five nigths in November 2005, when the observations were more intensive. Dates of observations are reported in each box. The solid line in V band - 4 Nov box results from a linear regression analysis. The solid line in H band - 8 Nov box connects the four points of the flare-like structure. In each box it is given a typical error bar. In V band - 4 Nov box the light curve of one comparison star is also plotted, with a fixed enhancement of 9 mJy.

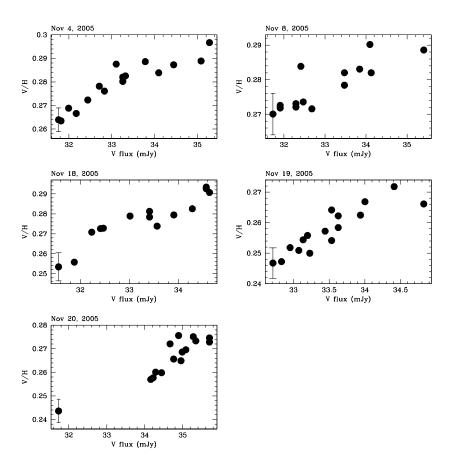

Figure 5. V/H flux ratio versus intensity for the five more intensively observed nights of epoch **3**. In each box a typical error bar is plotted.

| Night | 4/11 | 8/11 | 18/11 | 19/11 | 20/11 |
|-----------|----------------|----------------|----------------|----------------|----------------|
| Average H | 119.3±1.7 | 119.3±3.0 | 120.4 ± 2.1 | 124.5±2.8 | 130.8±3.0 |
| Average I | 39.1±0.6 | 36.4 ± 0.5 | 38.7 ± 0.6 | 38.7 ± 0.6 | 38.3 ± 0.7 |
| Average R | 38.5 ± 0.8 | 36.40±.8 | 37.3±0.5 | 38.0 ± 1.6 | 37.1±0.5 |
| Average V | 33.2±1.1 | 33.0±1.1 | 33.4±1.1 | 33.5±1.1 | 34.7 ± 0.1 |

Table 4. Average intensities and 1-sigma values for all filters for all five nights with more intensive observations in November 2005. All values are in mJy units.

as suggested in Fig. 4 H band - Nov 8 box, the time scale variability is as short as 1.5 h. Unfortunately the V light curve is too sparse to confirm the presence of the flare also in this band.

3.3. The NIR-Optical spectral energy distribution

We had six filter coverage (K,H,J,I,R,V) during three nights of Sept. 2005 (epoch 2) and representative SEDs for these nights are reported in Fig. 6.

The delays between exposures in the different filters are less than 20 minutes. Reddening corrections are less than 6% in V and have been neglected. A fit with a single power law yields $\alpha \approx 0.9$ and it is clearly not good. The main deviation derives from the J filter, exceeding substantially our photometric precision of about 10%. An improvement in the fit is obtained by using a broken power law with spectral indices $\alpha \approx 0.4$ for the IR data and $\alpha \approx 0.9$ for the optical data.

For comparison, we report in Fig. 7 the SED of June 29, 2006, exposure used for calibration purpose: its profile is rather similar to that of Sept. 2005.

At the other epochs the SED consists of 4 points (H, I, R, V), and in Figs. 8 and 10 we give representative examples of SEDs acquired on epoch 1 and 3. The time differences between observations at various filters are less than 20 minutes.

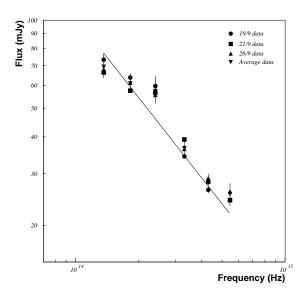

Figure 6. September 2005 spectra for observations including the K and J filters. The spectral fit on average data with a single power law yields a spectral index α =0.91 \pm 0.07.

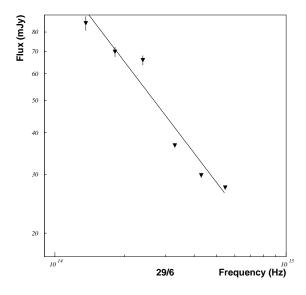

Figure 7. 29 June 2006 spectrum. The spectral fit with a single power law yields a spectral index α =0.90±0.16.

In Fig. 8, which refers to a low state, we report also the estimated contribution of the host galaxy, which was calculated adopting the H magnitude of the galaxy measured by Kotilainen et al. (1998) and the Mannucci at al. (2001) template spectrum for giant ellipticals. It is apparent that the contribution of the galaxy never exceeds 20% of the BL Lac signal. At the other epochs the contribution from galaxy is negligible and it is not relevant for explaining the excess in J with respect a single power law noted above. The epoch 2 photometry (Fig. 9) is compared with spectrophotometry obtained with the ESO 3.6m telescope by R. Falomo⁶ on July 25, 2001 (Sbarufatti et al. (2006)). The source was found in a similar, but somewhat lower brightness state and some deviations from a power law are apparent. The HRIV points at epoch 3 (Fig. 10) are roughly fitted by a single power law of $\alpha \approx 1.3$. In any case the comparison of the SEDs at the three epochs clearly indicate a softening with increasing intensity.

⁶ spectrum available at the ZBLLAC online library, http://www.oapd.inaf.it/zbllac

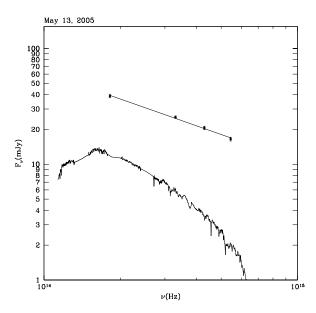

Figure 8. 13 May 2005 spectrum - epoch 1. We report also the spectrum of the host galaxy (see text). The spectral fit with a single power law yields a spectral index α =0.77 \pm 0.16.

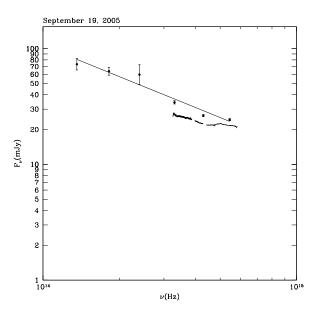

Figure 9. 19 September 2005 spectrum - epoch 2. For comparison we report the ESO 3.6m telescope spectrophotometry which correspond to a slightly lower state of the source. The spectral fit with a single power law yields a spectral index α =0.88 \pm 0.05.

4. Discussion

A collection of near-IR/optical SEDs of PKS2155-304 obtained by various authors at different epochs is presented in Fig. 11 and in Table 5. Our data encompass all those reported in the literature.

In the historical observations of PKS2155-304 the delays between exposures at different filters are typically of the order of hours, instead of about 10 minutes as in our data set. Comparing literature data with our data it is apparent that the maximum we observed on 20 November 2005 in the H filter light curve is the highest state ever reported in this band. Note that the V state was comparable with states reported in the literature, likely because the coverage of the source in the optical band is less sparse than that in the NIR. A most noticeable result of our photometry is the discovery of long term H-band variability, the amplitude of which is much larger than that in the optical.

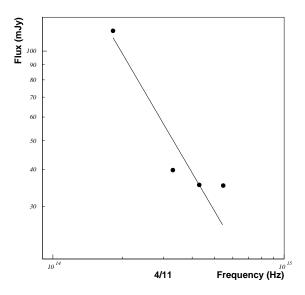

Figure 10. 4 November 2005 spectrum - epoch 3. The spectral fit with a single power law yields a spectral index α =1.32 \pm 0.25. Error bars are comparable with symbols size.

Table 5. Spectral index values and V values for all spectra plotted in Fig. 11. α vs V plot is reported in Fig. 12.

In Fig. 12 we plot the spectral index vs the V magnitude, as reported in table 5. There is no apparent correlation. It is noticeable however that the highest state in all bands (our observation of Nov 2005) corresponds to a rather soft spectral shape. This contrasts with the usual source behaviour of hardening with increasing intensity, as found in the UV-X-ray band (see Introduction). It contrasts also with the short time scale variability, as reported in section 3.2.

There is a general consensus that the blazar SED can be explained by the superposition of a synchrotron component, and an inverse Compton one due either to scattering off the synchrotron photons (synchrotron-self Compton, SSC), or to external photons like those of the broad line region or of a thermal disk (e.g. Tavecchio et al. 1998, Katarzynski et al. 2005). This results in a typical two-maxima shape of the blazar SED. In Fig. 13 we report examples of the SED modeling proposed for PKS 2155-304, on the basis of data taken in 1997. The models are detailed in Chiappetti et al. (1999). The object is a typical HBL, with the synchrotron peak in the soft X-rays.

A well known critical point of this model, is that the source size is essentially constrained by variability, and variability itself requires that the SED is constructed using simultaneous observations in all bands. A further step of the modelling consists in identifying the physical origin of the relativistic jet and of its variability, see e.g. Katarzynski & Ghisellini (2006). With this premise it is obvious that the optical-IR photometric study, non simultaneous with that in other regions of the SED, has only a limited relevance in clarifying the overall picture. However we would like to make some remarks. If the SSC models reported in Fig. 13 truly represent the behaviour of the SED in 1997, as suggested by the good match with the X-ray and TeV energy data, and if our 2005 optical-IR spectra are also due to the SSC mechanism, then the latter represent a different condition in the jet and point to different critical parameters within the SSC scenario. While the IR-optical spectrum in May 2005 (triangles) has the same shape as predicted in 1997, but different normalization, the November 2005 IR-optical spectrum is different in both

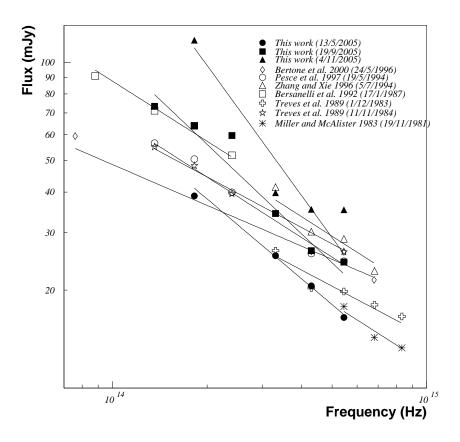

Figure 11. Different spectra of PKS2155-304 from observations at other epochs reported in the literature. Symbols correspond to following works: filled circles: this work (13/5/2005 data), filled squares: this work (19/9/2005 data), filled up triangles: this work (4/11/2005 data), open diamonds: Bertone et al. (2000; 24/5/1996 data), open circles: Pesce et al. (1997; 19/5/1994 data, the Hamuy & Maza (1989) calibration is used), open up triangles: Zhang and Xie (1996; 5/7/1994 data), open squares: Bersanelli et al. (1992; 17/1/1987 data), open crosses: Treves et al. (1989; 1/12/1983 data), open stars: Treves et al. (1989; 11/11/1984 data), asterisks: Miller and McAlister (1983; 19/11/1981 data). Spectral index values and V magnitudes for all data sets are reported in Table 5.

shape and normalization. The May 2005 observation suggests that the synchrotron peak may be located at a frequency similar to the one observed in 1997 (approximately between extreme UV and soft X-rays), the total energy being somewhat higher (about a factor 2, see Figure 13) than observed in 1997. The slope of the November 2005 spectrum suggests instead a much lower synchrotron peak energy, around the IR-optical domain or even redward, i.e. about 2-3 orders of magnitude lower than observed in 1997 and inferred in May 2005. While a variation of the synchrotron peak energy of this amplitude and on this time scale (the September 2005 slope is intermediate between those of May and November 2005, suggesting a monotonic change) it is not unprecedented in blazars (Mkn501 exhibited a similar variation in a much more rapid time scale, Pian et al. 1998), this would be the first observation of this kind in PKS 2155-304. Therefore, our interpretation is only tentative, although supported by the large observed IR variability.

Alternatively, in order to explain the optical-IR flux excess we observe in 2005 with respect to the SSC prediction based on the earlier multiwavelength data (Fig. 13), one could invoke a thermal component, possibly from hot dust associated with the "dusty torus" surrounding the central region of the active nucleus, as suggested in the cases of other blazars with excess in the optical-infrared band (De Diego et al. 1997, for blazar 3C 66A; Pian et al. 1999 for 3C 279; Pian et al. 2002, 2006, for blazar PKS 0537-441). However, this seems somewhat less likely, because high emission states, as observed by us, are expected to be dominated by non-thermal beamed relativistic radiation.

The continuation of this and other similar optical-IR studies, which have been proven to be promising but do not provide enough information for a physical interpretation of the data, requires that the observations are extended to other wavelengths. Simultaneous observations over a large wavelength range is the only tool to provide the necessary information for a physical interpretation of the observed variability of blazars. REM monitorings of the kind reported here could be an effective trigger to

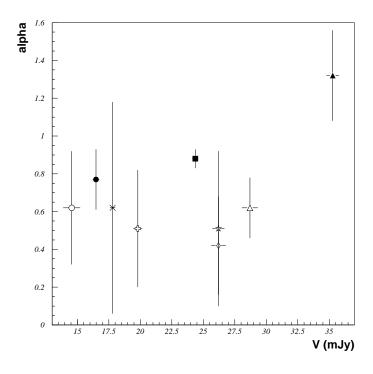

Figure 12. α vs V plot for data reported in Fig. 11. Symbols are the same as used in Fig. 11.

X-ray satellites, and programs along these lines are foreseen with SWIFT. Cross correlation procedures, which up to now have been limited mainly to the X-ray band (Zhang et al. 2005, 2006a, 2006b, Sembay et al. 2002, Edelson et al. 1995), would be extended to a much larger portion of the SED.

Appendix A: Table of observations

| Filter | Epoch (MJD) | Integr time s | Intensity mJy | Sigma |

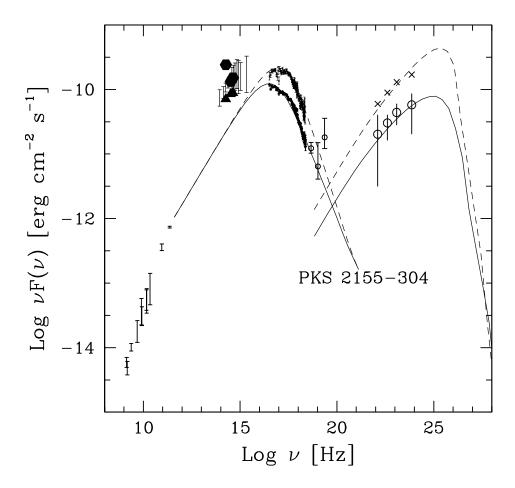

Figure 13. SED of PKS 2155-304 in two states, adapted from Chiappetti et al. (1999) (see the paper for details). Data from this work are also plotted. Filled triangles correspond to epoch **1** (13/5/2005 data), while filled hexagons belong to epoch **3** data (20/11/2005). Optical, UV and REM data are dereddened using E(B-V)=0.026 and parameters given by Cardelli et al. (1989).
